

Additional File 11. Tandem gene arrays in *A. adeninivorans*.

Table S11A List of tandem gene repeats in *A. adeninivorans*.

Tandem gene arrays (TGAs) were defined as genes of a given family separated by 0 to 10 intervening genes. After manual curation, 213 genes (including 12 pseudogenes) were assigned to 96 TGAs of one to six genes (see Table S11), most of the TGAs being in direct orientation (71.9%) as in other hemiascomycete yeasts. Compared to the whole set of CDSs, metabolic activities are over-represented among genes in TGAs (56% vs. 29%), as well as pseudogenes (5.6%, vs. 0.6%), (Table S11). Intron-containing genes on the contrary are under-represented in TGAs with seven genes only (3.3% vs. 10.6% for the whole gene set). A total of 62 tandem arrays without intervening gene were observed among TGAs. They involved 134 genes, 51 in direct repeats of up to 6 genes, 11 as inverted repeats.

TGA formation appears as a major mechanism for gene amplification of specific families of *A. adeninivorans*: all 8 members of the GL3C080 family, encoding a conserved NADPH oxidoreductase (Old Yellow Enzyme or Oye), occur in two uninterrupted tandems of 6 and 2 genes.

Figure S11B Examples of TGA duplication.

In the case of the two *A. adeninivorans* specific gene families GL3C4746 and GL3C4726, all members but one occur in direct pairs scattered on the same chromosome (GL3C4726) or on different chromosomes (GL3C4746). Blastn searches indicated that all tandems are highly conserved at the nucleotide level, both in coding and intergenic regions (Figure S11A1 and S11A2). It also suggested that single members in each family were likely part of an initial tandem from which the second member has been lost. Phylogenetic trees are compatible with a propagation of an ancestor tandem by successive replication, leading to independent differentiation of the two members of the pair in two well separated sub-families.

S11A1: GL3C4746

S11A2: GL3C4726

Figure S11C: Phylogeny of TGAs associated to GLC4705 inverted repeats.

A somewhat similar scenario may account for the formation of intermingled TGAs of members of the *A. adeninivorans* specific GL3C-4702, -4704, -4705, -4708 -4718 and -4726 families (main text and Figure 2). Eighteen out of the 25 members (including five pseudogenes) of the GL3C4705 family are arranged in a head-to-head orientation within seven blocks (numbered 1 to 7 as on Fig. 2) resulting from segmental duplications of an ancestral inverted repeat of two GL3C4705 members flanked by single copies of members of the GL3C4702, GL3C4708 and/or GL3C4704 families. Members of the GL3C4704 and GL3C4708 cluster together (see Fig S11B1 and S11B2) as expected if they derive from a unique initial capture event that was subsequently replicated along with the GL3C4705 pair. Such a trend is less obvious in the case of the members of the GL3C4702 families (Figure S11B3), which suggests that several capture events occurred in this case. Circled figures refer to associated GLC4705 inverted repeats on Figure 2.

S11C1: GL3C4704

S11C2: GL3C4708

S11C3: GL3C4702

Table S11A List of tandem gene repeats in *A. adeninivorans*.

IR = inverted repeat; DR = direct repeat

If repeats are interrupted by intervening genes, the number of intervening genes is indicated in parenthesis as nX (example: 1+2X+1 for a repeat interrupted by two intervening genes).

Figure S11B1 GL3C4746 family

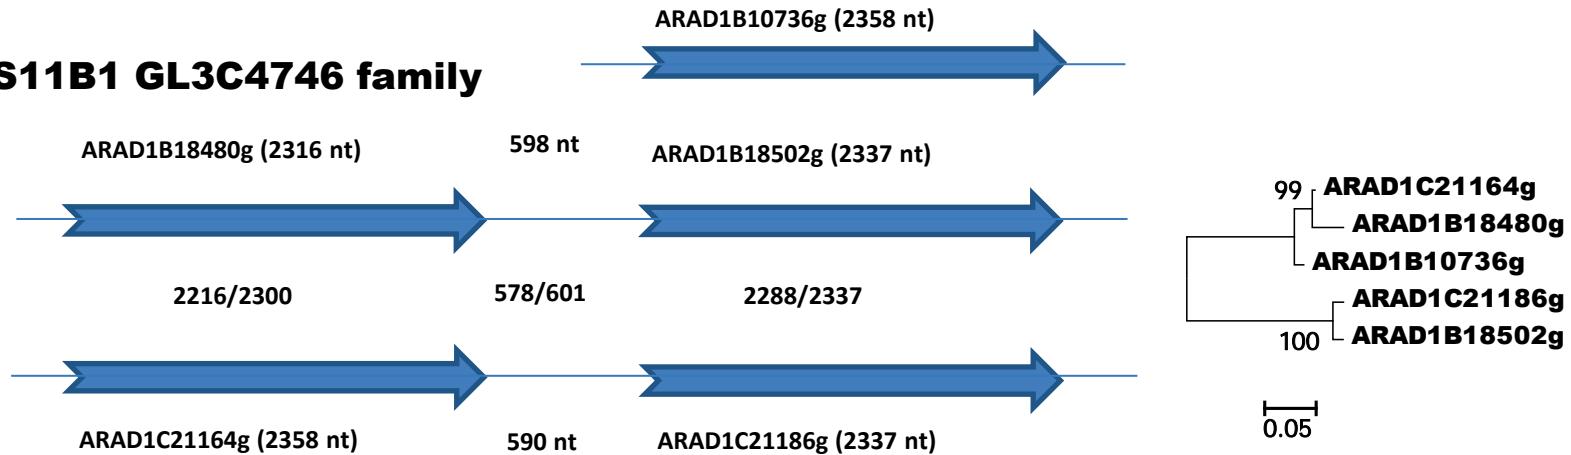

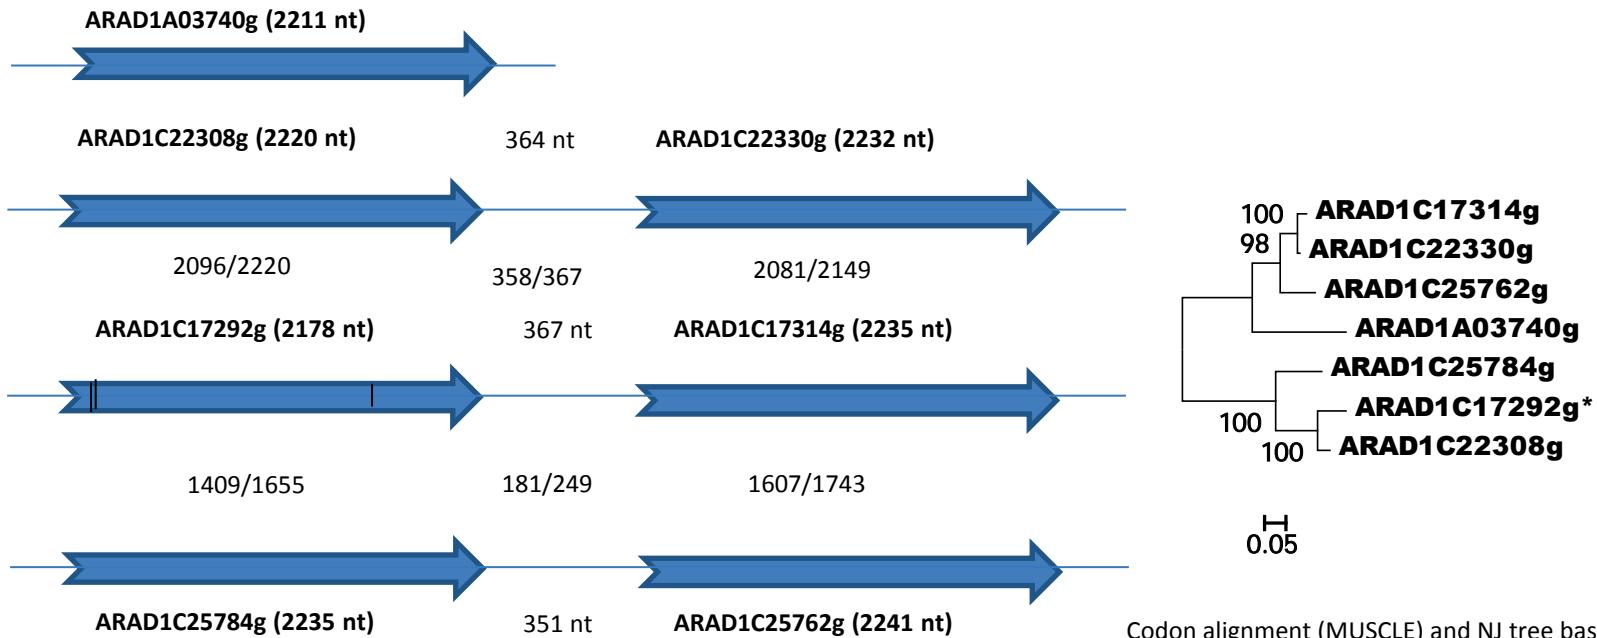

Figure S11B2 GL3C4726 family

Nucleotide identity within gene and intergenes was computed based on BLASTn alignments

Codon alignment (MUSCLE) and NJ tree based on 1st and 2nd codon position. Pseudogene indicated by *.
