46 ABSTRACT

Spumaretroviruses, commonly referred to as foamy viruses, are complex retroviruses belonging 47 to the subfamily Spumaretrovirinae, family Retroviridae, which naturally infect a variety of 48 animals including nonhuman primates (NHPs). Additionally, cross-species transmissions of 49 simian foamy viruses (SFVs) to humans have occurred following exposure to tissues of infected 50 NHPs. Recent research has led to the identification of previously unknown exogenous foamy 51 viruses, and to the discovery of endogenous spumaretrovirus sequences in a variety of host 52 53 genomes. Here, we describe an updated spumaretrovirus taxonomy that has been recently accepted by the International Committee on Taxonomy of Viruses (ICTV) Executive Committee, 54 55 and describe a virus nomenclature that is generally consistent with that used for other retroviruses, such as lentiviruses and deltaretroviruses. This taxonomy can be applied to 56 distinguish different, but closely related, primate (e.g., human, ape, simian) foamy viruses as 57 58 well as those from other hosts. This proposal accounts for host-virus co-speciation and crossspecies transmission. 59 60 61 62 63 64 65 66

67 1. Introduction

Spumaretroviruses belong to the subfamily *Spumaretrovirinae* in the family *Retroviridae*. 68 They are highly prevalent in animals of diverse non-primate mammalian families [Bovidae 69 70 (cloven-hooved ruminants), Felidae (cats), Equidae (horses and relatives), and Rhinolophidae 71 (horseshoe bats)], as well as nonhuman primates (NHPs), including apes, Old World monkeys (OWM), New World monkeys (NWM), and prosimians (1, 2). Members of the subfamily 72 Spumaretrovirinae, commonly referred to as foamy viruses, have a broad tissue and cell tropism 73 and virus infection is generally latent, except in some tissues of the oral cavity $((\underline{3}, \underline{4}))$. 74 The earliest reports of foamy virus isolates were of simian origin (NWM, OWM, and apes) 75 and were originally classified serologically using neutralization assays (5, 6). The first "human" 76 spumaretrovirus isolate was obtained from cultures of a human nasopharyngeal carcinoma in 77 78 1971 and was originally designated "human foamy virus (HFV)" (7, 8), but was later found to be of chimpanzee origin based upon sequence identity to chimpanzee foamy virus and renamed as 79 prototype foamy virus (PFV) $(\underline{6}, \underline{9})$. Cross-species transmissions of simian foamy viruses (SFVs) 80 to humans have occurred by exposure to fluids or tissues from infected NHPs (10-23). Although 81 foamy viruses are exogenously transmitted viruses, endogenous foamy virus sequences have 82 83 been identified and characterized in genomes of many species, including aye-aye (Daubentonia 84 madagascariensis), sloth (Choloepus hoffmanni), Cape golden mole (Chrysochloris asiatica), coelacanth (Latimeria chalumnae), platyfish (Xiphophorus maculatus), and zebrafish (Danio 85 *rerio*) (24-30). In fact, molecular evolution studies have indicated that spumaretroviruses have 86 co-speciated with their hosts for millions of years (24, 26, 31, 32). Recently, phylogenetic 87 analyses using amphibian and fish genomes have estimated the date of retrovirus emergence at 88 >450 million years ago (25) with foamy viruses inferred to be the most ancient retrovirus. A 89

90 recent increase in the number of foamy virus isolates and sequences using a variety of novel
91 molecular and genomic techniques highlights the need for updating and expanding
92 spumaretrovirus taxonomy (15, 31, 33-48).

93 The taxonomic history of Spumaretrovirinae has been based only on the few early virus isolates. Although "foamy virus" was discovered in rhesus monkey kidney cultures in 1955 (49), 94 95 simian foamy retroviruses, were not formally classified until the Second Report (1976) of the International Committee on Taxonomy of Viruses [ICTV], which assigned bovine syncytial virus 96 (BSV), feline syncytial virus (FSV), hamster syncytial virus (HSV), human foamy virus (HFV), 97 and simian foamy virus (SFV) to the "genus-less" subfamily Spumavirinae (50). In the Third 98 (1979) ICTV Report, the still genus-less subfamily Spumavirinae contained only four viruses 99 (BSV, FSV, HFV, and SFV) (51). By the Fifth (1991) ICTV Report, all three subfamilies 100 (Oncovirinae, Lentivirinae, and Spumavirinae) of the Retroviridae were abandoned and seven 101 genera created, including Spumavirus, which contained BSV, FSV, HFV, and SFV (52), with 102 HFV designated as the type species. This taxonomy was upheld in the Sixth (1995) ICTV 103 Report, but HFV was referred to as human spumavirus (53). The Seventh (2000) ICTV Report 104 105 for the first time differentiated between species and viruses. Chimpanzee foamy virus was designated the type species and chimpanzee foamy virus (formerly human spumavirus) was 106 assigned to it (according to ICTV rule, virus name is not italicized). The other species were 107 Bovine foamy virus (containing bovine foamy virus; formerly bovine syncytial virus), Feline 108 foamy virus (containing feline foamy virus, formerly feline syncytial virus), Simian foamy virus 109 110 1 (containing simian foamy virus type 1), and Simian foamy virus 3 (containing simian foamy virus type 3) (54). In the Eighth (2005) ICTV Report, based upon the distinct replication 111 pathway of foamy viruses, which contains features homologous to both retroviruses and 112

113 hepadnaviruses (55), the subfamily Spumaretrovirinae was reinstated for the genus Spumavirus. The species Simian foamy virus 1 was renamed Macaque simian foamy virus and the virus 114 assigned to this species, simian foamy virus 1, was renamed macaque simian foamy virus. 115 Similarly, the species Simian foamy virus 3 was renamed African green monkey simian foamy 116 *virus* and the virus in this species, simian foamy virus 3, was renamed African green monkey 117 simian foamy virus; the species Chimpanzee foamy virus was renamed Simian foamy virus and 118 119 the virus in this species, chimpanzee foamy virus was renamed simian foamy virus. In addition, 120 the species Equine foamy virus was established for equine foamy virus. No changes were made to Bovine foamy virus and Feline foamy virus (56). The most recent, Ninth (2011) ICTV Report, 121 122 lists six spumavirus species for six viruses (57), and this current classification is shown in Table 1. 123

The current taxonomy for spumaretroviruses is outdated as it does not accommodate new 124 foamy viruses discovered in NHPs of various species, including OWM and NWM (31, 36, 58). 125 Furthermore, formal nomenclature for designating virus isolates is lacking, particularly for 126 simian foamy viruses, which has led to some confusion in virus descriptions and references in 127 128 publications and retrieval of sequences deposited in public databases. The critical need for updating spumaretrovirus taxonomy and for developing a consensus nomenclature for different 129 foamy viruses was recognized by the scientific community and discussed at the International 130 Foamy Virus Conference held in 2014 in Puławy, Poland (59) and in 2016 in Paris, France (60). 131 Here, we present an updated and expanded spumaretrovirus taxonomy based upon current 132 133 knowledge that accounts for host-virus co-speciation and cross-species transmission. 134 Furthermore, the proposed virus nomenclature can be applied to all spumaretroviruses, including non-primate and primate viruses. 135

137	2. Updated 2017 spumaretrovirus classification
138	The recent increase in the number of primate and non-primate spumaretroviruses warranted
139	an update of the current ICTV classification as well as establishment of a more consistent
140	nomenclature. This updated taxonomy, which was proposed by the authors to the Executive
141	Committee of the ICTV on June 18, 2017, is shown in Table 2. The following changes were
142	proposed based on analyses of sequences of spumaretrovirus genomes available in public
143	databases:
144	• the existing genus <i>Spumavirus</i> was replaced by five genera named <i>Bovispumavirus</i> ,
145	Equispumavirus, Felispumavirus, Prosimiispumavirus, and Simiispumavirus because the
146	spumaretrovirus phylogeny largely reflects the host phylogeny (Fig. 1), supporting the
147	hypothesis of spumaretrovirus-host co-evolution (<u>18</u> , <u>24</u> , <u>26</u> , <u>31</u> , <u>32</u>);
148	• the established species <i>Bovine foamy virus</i> , <i>Feline foamy virus</i> , and <i>Equine foamy virus</i>
149	were included in the new genera Bovispumavirus, Felispumavirus, and Equispumavirus,
150	respectively. Additionally, the species Puma feline foamy virus was included in genus
151	Felispumavirus;
152	• a new species, Brown greater galago simian foamy virus, was included in a new genus
153	Prosimiispumavirus;
154	• the previously established species were included in the new genera, and new species were
155	established for previously unclassified spumaretroviruses. Species names were chosen
156	based upon the viral host animal names. The previous species simian foamy virus was
157	renamed Eastern chimpanzee simian foamy virus. The species Macaque simian foamy
158	virus and African green monkey simian foamy virus were renamed Taiwanese macaque

simian foamy virus and *Grivet simian foamy virus*, respectively, and together with

160

161

162

Eastern chimpanzee simian foamy virus were included in genus *Simiispumavirus*. Eleven additional NHP spumaretrovirus species were added to this genus. Each proposed species is represented by at least one virus for which a complete genome sequence has been

163 deposited in public databases.

In addition to the viruses included in the updated taxonomy submitted to the ICTV in 2017, 164 165 there are other foamy virus isolates, that are phylogenetically distinct from the currently included 166 ones and, were not included in the proposal because of the lack of a complete coding genome sequence. These are shown in Table 3 and are envisioned to be included in future taxonomic 167 168 updates, along with other available sequences at that time. It should be noted that the simian foamy virus Macaca fascicularis (SFVmfa) is also included in this table (and in Fig. 1) since it is 169 expected to be submitted in the next update based upon a published full-genome sequence (61). 170 171 Additionally, based upon recent discussions related to viruses identified by metagenomics, sequences that are distinct phylogenetically from the currently classified viruses and have been 172 completely sequenced in their coding regions may be classified officially by the ICTV even in 173 the absence of a virus isolate (62). 174

175

176 **3. Updated 2017 spumaretrovirus nomenclature**

Previously, different spumaretroviruses were named by adding three-letter lower-case
abbreviations to "SFV" (simian foamy virus) derived from the common names of the hosts from
which the viruses were isolated. For instance, SFV mac was used for simian spumaretroviruses
infecting macaques and SFV agm was used for simian spumaretroviruses infecting grivets
(African green monkeys, agm) (6). However, this general designation of viruses does not

distinguish strains infecting hosts of different species or subspecies. The genus *Macaca*(macaques) includes more than 20 species the members of which are distributed throughout Asia,
with one also in Africa, and the genus *Chlorocebus* (African green monkeys) includes six
species, the members of which are distributed across sub-Saharan Africa. The most confusing
virus name was "simian foamy virus", which referred to foamy viruses from all NHPs except
macaques and African green monkeys.

188 Here we propose a spumaretrovirus nomenclature similar to that used for simian 189 immunodeficiency virus and simian T-lymphotropic virus isolates. Accordingly, all spumaretrovirus names will contain the words "foamy virus" preceded by an adjectival classifier 190 191 indicating the host (e.g., bovine, feline, simian) followed by the name of the species, or in some cases subspecies, of the particular host. The virus host name and "foamy virus" are abbreviated 192 in capital letters (e.g., feline foamy virus is abbreviated FFV, simian foamy virus is abbreviated 193 194 SFV) followed by lower-case three-letter abbreviations for the host species name. These abbreviations are comprised of the first letter of the host genus and the first two letters of the 195 species or subspecies (e.g., simian foamy virus Macaca cyclopis is abbreviated SFVmcy) (Tables 196 2 - 3), or the first letter of the species or subspecies and the next unique letter, when the letters 197 are the same (e.g. simian foamy viruses isolated from New World primates such as 198 Leontopithecus chrysomelas and Leonthopithecus chrysopygus would be abbreviated as SFVlcm 199 and SFVlcp, respectively). In the case of an unknown host species, the first letter of the genus 200 name is followed by "xx" (italics letters). Virus isolate names are designated by using the virus 201 202 abbreviation followed by an underscore that appends additional, isolate-identifying information such as the host from which it was isolated (for instance, "hu" for human), isolate designation, 203 and other identifying information. For example, simian foamy virus Pan troglodytes 204

schweinfurthii, human isolate HSRV, clone 13 will be designated as SFVpsc_huHRSV.13, and
feline foamy virus Felis catus strain FUV7 will be designated as FFVfca_FUV7 (Table 4).
Similarly, in case of inter-species transmission involving nonhuman primates, SFV from western
red colobus monkey (*Philiocolobus badius badius*) isolated from a wild chimpanzee subspecies *Pan troglodyes verus* (63) will be designated as SFVpba_pveLeo. Furthermore, for recombinant
viruses (including naturally-occurring and those genetically-engineered), the designation "[RF]"
is included at the end (e.g., SFVmcy_FV34[RF] (64).

212

213 4. Conclusions

214 The updated and expanded spumaretrovirus taxonomy presented here was initially submitted to the ICTV on June 18, 2017, and is currently provisionally approved by the ICTV Executive 215 Committee. The proposal now awaits ratification by vote of the International Union of 216 217 Microbiological Societies (IUMS) Virology Division, which will occur in the first quarter of 2018. The new taxonomy format is easily expandable to accommodate new genera and species 218 219 for classification of newly discovered foamy viruses. Additionally, we have established a 220 spumaretrovirus nomenclature that considers host-virus co-speciation and cross-species transmission, and incorporates host animal species information and strain and/or animal 221 identification codes in spumaretrovirus names and their abbreviations. This collaborative effort is 222 aimed toward unifying classification and designations of spumaretroviruses to facilitate easy 223 comparisons of reported foamy virus isolates. 224

Figure 1. Foamy virus phylogeny reflects long-term virus-host co-speciation. Evolutionary relationships were inferred using 527 maximum likelihood analysis of an alignment comprising the polymerase gene (pol) and envelope gene (env) nucleotide sequences of 528 21 foamy viruses from diverse mammalian hosts. Branch tips are labeled with viral species names and the host common names; 529 brackets indicate common names for subfamily/group within the class Mammalia. Nodes are labeled with bootstrap support values 530 (based on 1000 replicates). An alignment (including insertions and deletions) beginning approximately in the middle of the pol gene 531 and extending to approximately the middle of the env gene was generated using the MUSCLE algorithm as implemented in Geneious 532 10.1.3. For reference, alignment corresponded to nucleotide position 5,089 - 7,927 of SFVpsc (NCBI accession number KX08159). 533 Alignment of all of the sequences are submitted in the Supplement. Unrooted tree was generated using PhyML with the HKY85 534 substitution model and the NNI search option. Tree was visualized using FigTree 1.4.2 (note that unrooted tree is shown as rooted for 535 ease of visualization). Topology is similar to those published by others (2, 24, 80). Input taxa and accession numbers were: SFVcni 536 (JQ867466); SFVcae (NC_010820); SFVmfa (LC094267); SFVmcy (NC_010819); SFVmmu (MF280817); SFVmfu (AB923518); 537 SFVpve (NC_001364); SFVpsc (KX08159); SFVptr (JQ867463); SFVggo (HM245790); SFVppy (AJ544579); SFVsxa (KP143760); 538 SFVcja (GU356395); SFVaxx (EU010385); SFVssc (GU356394); SFVocr (KM233624); FFVfca (Y08851); FFVpco (KC292054); 539 EFVeca (AF201902); BFVbta (NC 001831); CFVraf (JQ814855). 540 541
