#### 34 Abstract

35 Methanogenesis is an ancient metabolism of key ecological relevance, with direct impact on the evolution of Earth's climate. Recent results suggest that the diversity of methane 36 37 metabolisms and their derivations have probably been vastly underestimated. Here, by probing thousands of publicly available metagenomes for homologues of methyl-coenzyme 38 39 M reductase complex (MCR), we have obtained ten metagenome-assembled genomes

40 (MAGs) belonging to potential methanogenic, anaerobic methanotrophic and short-chain 41 alkane oxidizing archaea. Five of these MAGs represent under-sampled (e.g., 42 Verstraetearchaeota, Methanonatronarchaeia, ANME-1) or previously genomically undescribed (ANME-2c) archaeal lineages. The remaining five MAGs correspond to lineages 43 that are only distantly related to previously known methanogens and span the entire 44 45 archaeal phylogeny. Comprehensive comparative annotation significantly expands the 46 metabolic diversity and energy conservation systems of MCR-bearing archaea. It also 47 suggests the potential existence of a yet uncharacterized type of methanogenesis linked to 48 short-chain alkane/fatty acid oxidation in a previously undescribed class of archaea ('Ca. 49 Methanoliparia'). We redefine a common core of marker genes specific to methanogenic, 50 anaerobic methanotrophic and short-chain alkane-oxidizing archaea, and propose a possible 51 scenario for the evolutionary and functional transitions that led to the emergence of such 52 metabolic diversity.

53 Methanogenesis is an archaeal-specific metabolism of key relevance in the anaerobic degradation of organic matter and biogas production<sup>1,2</sup>. It is considered one of the most 54 ancient energetic metabolisms<sup>3,4</sup> with direct impact on the evolution of the Earth's climate 55 system<sup>5</sup>. Methanogens have been detected in virtually all types of anaerobic environments. 56 Until recently, all methanogens were thought to belong to two euryarchaeal clades, named 57 58 Class I and Class II methanogens<sup>6</sup>. The majority of Class I/II methanogens can grow by reducing  $CO_2$  into methane using  $H_2$  as an electron donor<sup>7</sup>. Several representatives of the 59 60 Methanosarcinales (Class II methanogens) use additional energetic substrates, including acetate and methylated compounds<sup>8</sup>. Methanosphaera spp. (Class I methanogens) are 61 restricted to the reduction of methanol with H<sub>2</sub><sup>9</sup>. Regardless of the encoded methanogenic 62 pathway, all members of Class I/II methanogens possess the H<sub>4</sub>MPT methyl-branch of the 63 64 Wood-Ljungdahl pathway (m-WL), the N<sup>5</sup>-Methyltetrahydromethanopterin:coenzyme M methyltransferase complex (MtrABCDEFGH or MTR), and the methyl-coenzyme M reductase 65 complex (McrABG or MCR)<sup>10</sup>. The same enzymes are present in ANaerobic MEthanotrophic 66 archaea (ANME) and are used in reverse to oxidize methane $^{11-13}$ . 67

68 Our understanding of the diversity and metabolic versatility of methanogenic archaea is undergoing a rapid transformation with the availability of additional isolates and 69 70 metagenome-assembled genomes (MAGs). This has revealed additional lineages only distantly related to Class I/II methanogens<sup>14–16</sup>, including Methanomassiliicoccales<sup>10</sup>, Methanofastidiosales<sup>17</sup>, Methanonatronarchaeia<sup>18</sup> and Verstraetearchaeota<sup>19</sup>. A striking 71 72 73 characteristic of these recently described methanogens is the absence of the MTR complex, 74 a partial or missing m-WL pathway, and the presence of specific methyltransferases for the 75 utilization of methylated compounds. Accordingly, they are predicted to be limited to reduce 76 methylated compounds with H<sub>2</sub> for methanogenesis, which was experimentally validated for Methanomassiliicoccales<sup>20</sup> and Methanonatronarchaeia<sup>18</sup>. Interestingly, the implication of a 77 divergent McrABG-like complex in the oxidation of short-chain alkanes (butane, propane) 78 has been demonstrated in two representatives of a recently described euryarchaeal order, 79 the 'Ca. Syntrophoarchaeales'<sup>21</sup>. Divergent MCR sequences were also found in two members 80 of the Bathyarchaeota<sup>22</sup> (TACK superphylum), in the GoM-Arc1 (a lineage within the 81 82 Methanosarcinales)<sup>23</sup>, and from environmental samples<sup>24</sup>. Altogether, this suggests that 83 methanogens, anaerobic methanotrophs and short-chain alkane oxidizers may have an even 84 wider phylogenetic and environmental distribution than previously anticipated, provoking 85 new questions on the diversity and evolution of these metabolisms.

86 87

# 88 Results and Discussion

#### 89

# 90 Additional lineages of archaea with an MCR or MCR-like complex

91 To identify previously undescribed lineages of potential methanogens, anaerobic 92 methanotrophs and short-chain alkane oxidizers, we probed available metagenomes from 93 the JGI/IMG database for McrA homologues and identified sequences distantly related to 94 well characterized lineages (Methods). Ten MAGs were reconstructed from the corresponding metagenomes sourced from a wide range of anoxic environments including 95 an inland petroleum reservoir from Brazil, oil seeps from USA<sup>25</sup>, soda lake sediments from 96 97 Russia, and hot-springs from China and USA (Table 1). Nine of the ten MAGs had an 98 estimated completeness ranging from 78.4 to 94.4%, and one was only 51.5% complete. 99 Estimated contamination (without strain heterogeneity) ranged from 0 to 3.3%.

100 Four MAGs represent three previously undescribed lineages only distantly related to 101 known methanogenic/methanotrophic archaea (Fig. 1): NM1 (NM1a and NM1b MAGs) branches within the Methanotecta superclass<sup>15</sup>, between Archaeoglobales and the clade 102 formed by 'Ca. Syntrophoarchaeales' and 'Ca. Methanophagales'<sup>15</sup> (ANME-1); NM3 branches 103 within the Acherontia superclass<sup>15</sup>, at the base of the clade formed by the non-104 methanogenic Theionarchaea<sup>26</sup> and 'Ca. Methanofastidiosa' (former WSA2/Arc1); NM4 105 106 branches within the TACK superphylum and is related to Korarchaeum cryptofilum. In the 107 NM4 MAG, the markers for methane metabolism are present on two contigs with a lower 108 coverage than the other contigs and contain few genes related to Korarchaeum. However, 109 an independent study supports that these contigs belong to the same organism, 110 provisionally named "Candidatus Methanodesulfokores washburnensis" for its methane-111 and sulfur-cycling capacities (McKay et al., submitted). One additional MAG (NM2) was too 112 partial to assess its phylogenetic placement.

Finally, five MAGs correspond to currently under-sampled archaeal lineages: a deepbranching Verstraetearchaeota, a third Methanonatronarchaeia, a second '*Ca*. Methanophagales' (ANME-1), a second GoM-Arc1 (showing a close relationship with the methanotrophic Methanoperedens), and the first representative of ANME-2c (Fig. 1).

117

### 118 Phylogeny and functional inference of MCR/MCR-like complexes

119 To investigate the evolutionary relationships and characteristics of the MCR complexes 120 identified in this study, we built a phylogeny based on a concatenated alignment of McrABG subunits. This phylogeny is in overall agreement with recently published ones<sup>16,18</sup>. Three 121 MAGs (NM1a, NM1b and GoM-Arc1-GOS) encode alternative McrABG-like complexes that 122 123 cluster with those of 'Ca. Syntrophoarchaeum' and Bathyarchaeota (Fig. 2A, in blue). The 124 presence of an MCR-like complex and the absence of a canonical MCR in GoM-Arc1-GOS are consistent with the recent description of a MAG of this lineage<sup>23</sup>, and represent so far a 125 126 unique feature within the Methanosarcinales.

127 The remaining MAGs harbour canonical MCR complexes (Fig. 2A), branching next to their closest MCR-bearing neighbors in the reference archaeal phylogeny (Fig. 1), suggesting 128 129 no recent horizontal gene transfers (HGT). The clustering of NM3 with Methanofastidiosa 130 supports an early presence of methanogenesis in the Acherontia. The clustering of NM4 with 131 Verstraetearchaeota, support that it is a genuine methanogenic/methanotrophic 132 representative of the TACK. The separate branching of ANME-2c from the other ANME-2 133 lineages suggests that anaerobic methane oxidation in Methanosarcinales emerged multiple 134 times independently from methanogenic ancestors. Interestingly, both NM1a and NM1b 135 encode, in addition to the McrABG-like complex, a canonical MCR complex branching at the 136 base of Class II methanogens, consistently with the reference phylogeny. The coexistence of 137 MCR and MCR-like complexes in the same archaeon has never been observed before and 138 brings into question the metabolism of this lineage (see below).

139 It is striking to observe that most of the predicted or experimentally proven methyl-140 dependent hydrogenotrophic methanogens are closely related in the MCR tree (Fig. 2A, in 141 red), irrespective of their placement in the reference phylogeny (Fig. 1). This might be the 142 consequence of ancient exchanges of the MCR complex among these lineages, whose 143 direction is hard to define. Nevertheless, some more recent transfers may be identified. For 144 example, 'Ca. Methanophagales' (ANME-1) MCRs branch far from their Methanotecta 145 relatives, and might have acquired their MCR complex from a methanogenic member of the 146 Acherontia.

147 The clustering of MCR-like homologues belonging to distantly related lineages (Fig. 148 2A, in blue) is also puzzling. This might be due to HGT and/or tree reconstruction artefacts 149 linked to their high sequence divergence with respect to canonical MCRs, exemplified by 150 their longer-than-average branches. Such divergence is probably related to a change in function, as MCR-like complexes are involved in activating short-chain alkanes (butane and 151 propane) in 'Ca. Syntrophoarchaeum'<sup>21</sup>. Accordingly, several residues playing an important 152 153 role in canonical MCR, either by interacting with cofactors, forming the catalytic site cavity 154 wall or being post-translationally modified, are not conserved in 'Ca. Syntrophoarchaeum' 155 sequences (Fig 2B). The replacement of large aromatic residues (e.g. Phe330, Tyr333, Tyr444, Tyr446) present in the cavity wall of canonical MCR<sup>27</sup> by smaller ones in 'Ca. 156 Syntrophoarchaeum' MCR-like complexes could have occurred to accommodate 157 158 butane/propane (larger substrate than methane) in the catalytic site (Fig. 2B). The presence 159 of smaller amino acids at these positions in NM1 and Bathyarchaeota MCR-like complex 160 suggest a similar function in short-chain alkane oxidation. Finally, the MCR-like sequences of 161 GoM-Arc1 show fewer modifications at these sites, suggesting the utilization of a smaller 162 alkane, possibly ethane or methane.

163

### 164 Expanded diversity of methyl-dependent hydrogenotrophic methanogens

165 The NM3 and NM4 MAGs share several similarities with the recently discovered order-level 166 lineages of methanogens that were proposed or experimentally proven to perform methyldependent hydrogenotrophic methanogenesis<sup>10,17–19</sup> (Fig. 3, Supplementary Table 1). First, 167 168 these relatively complete MAGs (85,5% completeness) lack at least 24 genes coding for the 169 MTR complex,  $H_4MPT$  biosynthesis, and the  $H_4MPT$  methyl-branch of the WL pathway, 170 otherwise present in all Class I/II methanogens (Supplementary Table 1). Second, they 171 encode [Ni-Fe] hydrogenases and methyltransferases with the potential to support 172 methanogenesis from methanol (MtaABC) in NM3 and NM4 and methanethiol (MtsAB) in 173 NM3 (Fig. 3; Supplementary Table 1). Interestingly, energy conservation complexes of NM3 are mostly similar to Methanofastidiosales<sup>17</sup> (Supplementary Fig. 1), their closest related 174 methanogens in the reference phylogeny (Fig. 1). Altogether, this suggests that NM3 and 175 176 NM4 rely on methyl-dependent hydrogenotrophic methanogenesis (Fig. 3; Supplementary 177 Discussion for details on energy conservation in NM3 and NM4).

178 The predicted methanogenesis pathway in Verst-YHS (Verstraetearchaeota) and 179 Mnatro-ASL (Methanonatronarchaeia) MAGs also supports methyl-dependent hydrogenotrophic methanogenesis (Fig. 3, Supplementary Table 1), as described in the first 180 genomic assemblies for these lineages<sup>18,19</sup>. However, comparison of the energy conservation 181 182 enzymes in the seven currently available Verstraetearchaeota (order Methanomethyliales) suggests an alternative model than previously described<sup>19</sup> (Fig. 3, Supplementary Table 1). 183 Indeed, we found that all Methanomethyliales MAGs (95% average completeness) lack the 184 185 HdrA/MvhD and possibly MvhAG subunits of the electron-bifurcating complex 186 HdrABC/MvhADG, suggesting that this complex is absent in these archaea. In contrast, we 187 identified in these genomes a gene cluster encoding a potential complex composed of a 188 membrane-bound hydrogenase and of HdrBC (tentatively named Energy-converting 189 Hydrogenase D or Ehd; Supplementary Fig. 2). We propose that this complex could be 190 involved in a previously unreported mode of energy conservation associated with 191 methanogenesis (Fig. 3; Supplementary Discussion).

192

#### 193 Insights into methane and short-chain alkane oxidizers

GoM-Arc1-GOS, ANME-1-THS and ANME-2c MAGs possess a WL pathway and lack the 194 195 methyltransferases and [Ni-Fe] hydrogenases required for methylotrophic and 196 hydrogenotrophic methanogenesis, respectively (Fig. 3; Supplementary Table 1), similar to 197 all available MAGs of methanotrophs and short-chain alkane oxidizer (Supplementary Fig. 3). Although they encode an AMP-producing acetyl-CoA synthetase (Acs) which is used for 198 199 aceticlastic methanogenesis in Methanosaeta spp., they could rather use it for acetate assimilation<sup>11</sup>. Comparison with methanotrophs and short-chain alkane oxidizers also reveals 200 201 a common core of enzymes for energy conservation, comprising the F<sub>420</sub>H<sub>2</sub>:quinone (or 202 phenazine) oxidoreductase (Fqo/Fpo) and a potential electron confurcating complex (HdrABC/MvhD/FdhB<sup>28</sup>) coded by a conserved gene cluster (Supplementary Fig. 4). ANME-2c 203 and GoM-Arc1-GOS encode 17 and 10 multiheme c-type cytochromes respectively, 204 205 supporting the importance of direct electron transfer to syntrophic partners in anaerobic methane<sup>29,30</sup> and short-chain alkane oxidation<sup>21</sup> metabolisms (Supplementary Fig. 3; 206 207 Supplementary Table 1).

208 ANME-1-THS MAG is the first sequenced representative of a "Land clade" within the 209 'Ca. Methanophagales' (Supplementary Fig. 5), suggesting different adaptations to environmental conditions than members of the ANME-1b clade, which are mainly from 210 211 marine methane seeps. ANME-1-THS differs from the ANME-1b MAG<sup>31</sup> by the presence of a 212 bacterial-like Rnf complex that could couple the NAD:ferredoxin oxidoreduction with 213 chemiosmotic gradient generation/utilisation (Fig. 3; Supplementary Fig. 6; Supplementary 214 Discussion). If these genes are not in the missing region of this MAG, ANME-1-THS might also 215 differ from the other ANMEs by the lack of multiheme c-type cytochromes to transfer 216 electrons from methane oxidation to a syntrophic partner (Fig. 3; Supplementary Fig. 3). 217 Alternatively, two PsrABC-like complexes, including a molybdenum/selenocysteinecontaining dehydrogenase subunit, could be involved in the reduction of inorganic 218 compounds such as polysulfide/elemental sulfur<sup>32,33</sup> (Fig. 3). This contrasts with ANME-1b 219 220 MAG which misses the membrane integral (PsrC-like) subunit needed to transfer electrons 221 from membrane-associated electron transporters (Supplementary Fig. 3). These 222 characteristics might indicate growth of ANME-1-THS without bacterial syntrophs.

223 The gene content of GoM-Arc1-GOS is consistent with the recent description of the first member of the GoM-Arc1 lineage<sup>23</sup>. While GoM-Arc1 members encode an MCR-like 224 complex possibly involved in short-chain alkane oxidation (Fig. 3), they lack the beta-225 oxidation pathway proposed to be involved in butane/propane utilization in 'Ca. 226 Syntrophoarchaeales'<sup>21</sup> (Supplementary Fig. 3). If GoM-Arc1 members are capable of 227 oxidizing ethane ( $CH_3CH_3$ ), as suggested by the fewer modifications observed in the catalytic 228 229 site of its MCR-like complex relative to canonical MCRs (Fig. 2), the oxidation of the ethyl-230 group would lead to an acetyl- group that could directly enter the oxidative WL pathway, 231 making the beta-oxidation pathway unnecessary (Fig. 3; Supplementary Discussion). With 232 the presence of Fqo, HdrABC/MvhD/FdhB, multiheme c-type cytochromes, and HdrDE 233 (Supplementary Table 1), the energy conservation system associated with this potential 234 ethane-oxidation metabolism in GoM-Arc1 would mostly resemble that associated with 235 methanotrophy in their closely related ANME-2 lineages (Supplementary Fig. 3). The 236 question remains whether the MCR-like homologs of GoM-Arc1 could also be capable of 237 methane oxidation.

238

#### 239 A previously uncharacterised type of methanogenesis?

240 The two NM1 MAGs represent the first archaea predicted to encode both an MCR and an 241 MCR-like complex (Fig. 2), suggesting that they might be potentially capable of both 242 methane and short-chain alkane metabolisms (Fig. 4; Supplementary Table 1). Interestingly, 243 while both NM1 MAGs encode the MTR and the m-WL pathway similarly to Class I/II 244 methanogens, they lack the [Ni-Fe] hydrogenases (MvhA and FrhA) and methyltransferases 245 needed for hydrogenotrophic and methylotrophic methanogenesis, respectively. They also 246 diverge from Class I/II methanogens by the replacement of the F<sub>420</sub> dependent methylene-247 tetrahydromethanopterin dehydrogenase (Mtd) by MtdB, which relies on NAD(P) redox 248 cofactor in *Methylobacterium extorquens*<sup>34</sup>.

249 Beyond the presence of an MCR-like complex, the potential ability of NM1 for short-250 chain alkane oxidation is also suggested by the presence of a complete beta-oxidation 251 pathway with several gene copies per step, and a complete WL pathway (including CODH/ACS) as in 'Ca. Syntrophoarchaeales'<sup>21</sup>. In addition, NM1 encode multiple long-chain 252 253 fatty acid acyl-CoA synthases (FadD-like), not present in 'Ca. Syntrophoarchaeales'. Long 254 chain fatty acids (LCFA) activated with these enzymes can enter the beta-oxidation pathway. 255 NM1a and NM1b also encode multiple AMP-forming acetyl-CoA synthetase (Acd) to 256 generate ATP from LCFA degradation. These enzymatic redundancies suggest a versatility 257 toward substrates, as previously proposed for Syntrophus aciditrophicus<sup>35</sup> and Archaeoglobus fulgidus<sup>36</sup>. Consistently, analysis of the environmental distribution of NM1 258 (Supplementary Fig. 7) reveals their common association with anoxic hydrocarbon-rich 259 260 environments including methane seeps and oil-rich environments, where short-chain alkanes and long-chain carboxylic acids can be present in substantial concentrations<sup>37,38</sup>. In 261 particular, NM1a and NM1b originate from an enrichment culture based on petroleum fluids 262 263 and from a natural oil seep.

264 In addition to this potential wide substrate range, NM1 also contrast with 'Ca. 265 Syntrophoarchaeales' in terms of energy conservation by lacking homologues of the 266 NADH/ $F_{420}$ H<sub>2</sub>:quinone oxidoreductase (Nuo/Fqo) and multiheme c-type cytochromes (Fig. 4; 267 Supplementary Table 1). Also, NM1 contain an Rnf complex potentially using NAD instead of 268 menaguinone for ferredoxin oxidoreduction, similarly to ANME-1-THS (Supplementary Fig. 6; 269 Supplementary Discussion). In the absence of membrane-bound enzymes involved in 270 oxidoreduction of lipid-soluble electron carriers, of multiheme c-type cytochromes for direct 271 interspecies electron transfer, of confurcating [Fe]-hydrogenase for interspecies  $H_2$ transfer<sup>39</sup>, and of enzymes involved in dissimilatory reduction of inorganic compounds, the 272 273 nature of the terminal electron acceptor coupled to alkane/LCFA oxidation remains elusive. 274 Although both MAGs are mostly complete (~90%), it cannot be excluded that some of these 275 enzymes are coded in their missing regions, or that an alternative way to transfer electrons 276 to a terminal acceptor exists (e.g. utilisation of the assimilatory-type sulfite reductase 277 present in both MAGs for dissimilatory reduction of sulfite, direct electron transfer not 278 relying on cytochromes, or utilization of cytochromes produced by a syntrophic partner). 279 Alternatively, we speculate that in NM1, methanogenesis involving the canonical MCR 280 complex could act as a sink for the electrons produced during alkane and LCFA oxidation. 281 Several electron-bifurcating/confurcating complexes encoded in the two NM1 MAGs 282 (Supplementary Fig. 8) together with the Rnf complex could be involved in this metabolism. 283 The conversion of alkane and LCFA into CH₄ and acetate is thermodynamically feasible but 284 was only reported to occur through syntrophic partnerships between a bacterium (performing the beta-oxidation) and a  $H_2$ -consuming methanogen<sup>40,41</sup>, and it thus remains to 285 be proven experimentally whether this can occur in a single organism. 286

Based on the presence of methane and short-chain alkane/fatty acid-related enzymes and the preferential association with hydrocarbon-rich environments, we propose the provisional class *'Candidatus* Methanoliparia', with *'Candidatus* Methanoliparum thermophilum' for NM1a and *'Candidatus* Methanolliviera hydrocarbonicum' for NM1b (see Supplementary Discussion for full taxonomy and nomenclature).

292

## 293 A core of markers related to methane and short chain-alkane metabolisms

294 A group of 38 genes present in most methanogens and absent from most other organisms, 295 generally referred to as "methanogenesis core markers", was previously defined from Class I/II methanogen genomes<sup>42,43</sup> (Supplementary Table 2). Half of them have an unknown 296 function. The others correspond to MCR and MTR subunits, enzymes for biosynthesis and 297 298 activation of the F<sub>430</sub> prosthetic group of MCR, and post-translational modifications in the McrA catalytic site<sup>44,45</sup>. We reassessed the occurrence of these markers in the ten assembled 299 300 MAGs as well as reference genomes covering all recently discovered lineages of 301 methanogens, methanotrophs and short-chain alkane oxidizers (Table 2).

302 Our analysis shows that some markers are no longer universal in Class I/II 303 methanogens (e.g. m37, 38). Also, many marker genes shared by all or most Class I/II 304 methanogens were predicted to be nonessential in *Methanococcus maripaludis* S2<sup>46</sup> (Table 2). These non-universal and nonessential genes could possibly be involved in fine-tuning of 305 methanogenesis (e.g. post-translational modification of MCR<sup>47</sup>) or in its regulation under 306 307 specific environmental conditions that are not encountered by all methanogens. For 308 example, m21 and m24 are missing in several methanogens from nutrient-rich 309 environments, such as Methanobrevibacter, Methanosphaera and Methanocorpusculum, 310 and could be involved in regulatory processes related to changes in substrate/nutrient 311 availability.

All the lineages of predicted and experimentally proven methyl-dependent 312 hydrogenotrophic methanogens<sup>17–19</sup> lack numerous markers (Table 2), similarly to what was 313 previously noted in Methanomassiliicoccales<sup>48</sup>. These markers correspond to MTR complex 314 subunits (m27-31), an McrA post-translational modification enzyme (m33)<sup>45</sup> and several 315 uncharacterized markers that are mostly nonessential in *M. maripaludis*<sup>46</sup> (Table 2). The 316 317 existence of the same pattern in NM3 and NM4 supports our inference of a potential 318 methyl-dependent hydrogenotrophic methanogenesis. Finally, Bathyarchaeota BA1 and BA2<sup>22</sup> which were described as methyl-dependent hydrogenotrophic methanogens<sup>22</sup> but 319 320 possess an MCR-like complex instead of the canonical MCR (Fig. 2), lack almost all methanogenesis markers (Table 2), questioning their actual metabolism. 321

Several homologues of the methanogenesis markers are also known to be present in non-methanogenic archaea. This is the case of the MCR/MCR-like (m1-3) and MTR (m27-31) complexes in archaeal methanotrophs<sup>7</sup> and GoM-Arc1<sup>23</sup>, as well as the MCR-like complex in '*Ca*. Syntrophoarchaeales'<sup>21</sup>. Based on our analysis, archaeal methanotrophs and short-chain alkane oxidizers also appear to possess numerous markers previously exclusively associated with methanogenesis (Table 2), supporting the common origin and functional links of these metabolisms.

In addition to the MCR/MCR-like complex subunits, the most specific and conserved markers in all lineages of methanogens, methanotrophs and short-chain alkane oxidizers appear to be the genes involved in the biosynthesis (nflD/cfbD, murD/cfbE and possibly  $mcrD^{49}$ ) and activation (atwA and possibly  $mcrC^{50}$ ) of the F<sub>430</sub> prosthetic group of MCR, along with six genes encoding uncharacterized proteins (m4 to m9) (Table 2). These six genes are co-localized in most genomes (Supplementary Fig. 9) and are among those that were predicted to be co-transcribed in *Methanolobus psychrophilus* R15<sup>51</sup>, suggesting they operate in a common process. These six marker enzymes do not co-purify with MCR<sup>50</sup>. However, their phylogeny (Supplementary Fig. 10) and their restriction to archaea having MCR or MCR-like complexes strongly suggest they are involved in essential aspects of the regulation, folding and/or function of the respective holoenzymes (Supplementary Discussion).

Finally, several markers are present in archaeal lineages without MCR/MCR-like complexes (Supplementary Table 3) and are possibly remnants of an ancestral methanemetabolism (Supplementary Fig. 11-13; Supplementary Discussion).

Taken together, these observations indicate that none of the previously defined methanogenesis markers are unique to methanogens but are rather more generally indicative of metabolisms involving MCR or MRC-like complexes, including methanogenesis, methanotrophy, and short-chain alkane oxidation. Elucidating the roles of these markers (MCR-Associated Markers or MAM) will be essential not only for understanding methanogenesis, but also anaerobic methanotrophy and short-chain alkane oxidation in archaea.

351

# 352

#### 353 **Evolution of methane and short-chain alkane metabolisms**

Our results significantly extend recent data by highlighting the overwhelming presence of lineages with an MCR or MCR-like complex in the Archaea (Fig. 1). This supports an early origin of methanogenesis in this domain of life, and multiple losses of this metabolism during archaeal diversification<sup>4,14,18,52</sup>.

358 The sharing of a common set of genes (Table 2) clearly indicates that methanogens, 359 anaerobic methanotrophs and short-chain alkane oxidizers are evolutionarily linked. 360 However, it remains unclear which type of metabolism is the most ancient, and what evolutionary and functional transitions led to such diversity<sup>14</sup>. The antiquity of the WL 361 pathway<sup>53,54</sup>, and the recent proposal that the root of the archaeal tree might lie in between 362 363 Class I and II methanogens<sup>52</sup>, would suggest that CO<sub>2</sub>-dependent hydrogenotrophic 364 methanogenesis is the ancestral type of methanogenesis. Nevertheless, the growing 365 diversity of methyl-dependent hydrogenotrophic methanogens, including this work (Fig. 1 in 366 red), indicates that this metabolism has been largely overlooked. Its origin and evolutionary 367 relationship with CO2-dependent hydrogenotrophic methanogenesis remain unclear. The 368 fact that it is a simpler metabolism, requiring fewer genes than CO2-dependent 369 hydrogenotrophic methanogenesis might suggest its earliest origin. However, it may also 370 signify that it could have emerged later through loss of the WL pathway and/or HGT, as 371 suggested by the grouping of most archaea sharing this metabolism in the phylogenies of 372 MCR (Fig. 2A) and of m4 to m9 markers (Supplementary Fig. 10). Also, the clustering of NM4 373 with Verstraetearchaeota on a separate and well-supported clade in the MCR tree (Fig. 2A) is 374 compatible with a possible inheritance of this metabolism from the last archaeal common 375 ancestor, even under the classical root in between Euryarchaeota and the TACK. However, 376 the possibility of an acquisition through ancient HGT cannot be excluded at present. More 377 insights into the ancestral type of methanogenesis might also be gained from re-examination of the root of the archaeal tree<sup>52</sup> including all recently discovered archaeal lineages. 378

The phylogenetic placement of the ANME lineages (Fig. 1), strongly suggests that the capabilities for anaerobic methanotrophy emerged multiple times independently during archaeal diversification. In the Methanosarcinales this could have occurred relatively recently and repeatedly by reversal of methanogenesis, possibly through switch of function of a resident canonical MCR, leading to the different ANME-2 (Fig. 2A) and possibly ANME-3 lineages. The pool of genes associated with energy conservation in methanogenic and methanotrophic Methanosarcinales is in fact relatively similar<sup>55</sup> (Fig. 3 and Supplementary Fig. 3) and some methanogenic Methanosarcinales encode c-type multiheme cytochromes<sup>11</sup> providing the necessary background for electron transfer in AOM archaea.

388 The identification and experimental demonstration of the capacity for oxidation of 389 short-chain fatty-acids (butane, propane) by a divergent MCR-like complex in the Synthrophoarchaeales<sup>21</sup> is among the most interesting findings of the recent years in the 390 391 field of environmental microbiology. Our results extend the distribution of these MCR-like 392 complexes in the archaea (Fig. 2A), and therefore also of potential short-chain alkane 393 oxidation capabilities (Figs. 3 and 4). The rapid evolutionary rates of MCR-like homologues 394 coupled to the change of key residues (Fig. 2B) suggest that these complexes might have 395 arisen from canonical MCRs through modifications in the catalytic site to accommodate 396 larger hydrocarbons than methane. Transitions between anaerobic methanotrophy and 397 short-chain alkane utilisation could have occurred in both directions as suggested by i) the 398 phylogenetic relationships between 'Ca. Methanophagales' and 'Ca. close 399 Syntrophoarchaeales' and the position of GoM-Arc1 within a clade comprising ANME-400 2a/ANME-2d (Fig. 1), ii) the proposed mechanism of alkane activation in their MCR/MCR-like 401 complexes<sup>21</sup>, iii) their very similar modes of energy conservation (Supplementary Fig. 3), and 402 iv) their numerous shared markers (Table 2). If GoM-Arc1 is a short-chain alkane oxidizer, as 403 suggested by its MCR-like complex, this capacity could have emerged from methanotrophy. 404 Conversely, 'Ca. Methanophagales' (ANME-1) might have shifted from short-chain alkane 405 oxidation to methanotrophy after acquisition of their MCR through HGT (Fig. 2). Finally, the 406 first report of co-existence of an MCR and an MCR-like complex in members of the "Ca. 407 Methanoliparia" class opens up the possibility of an additional type of methanogenesis 408 associated with alkane and/or LCFA oxidation.

Further exploration of archaeal lineages with an MCR/MCR-like complex and their experimental characterization will lead to a more complete understanding of methane metabolisms and their derivations, as well as their environmental impact.

412

413

### 414 Methods

415

## 416 Metagenomic database probing and contig binning

417 Contigs of 6108 metagenomes publicly available on the IMG/JGI database in April 2017 were 418 screened for the presence of COG4058, corresponding to McrA, using search tools of the 419 database. 819 contigs containing an McrA sequence with a minimal length of 750 bp were 420 downloaded. The McrA sequences present on these contigs were aligned on those of 188 published genomes by using Mafft<sup>56</sup> (mafft-linsi) and were trimmed with BMGE<sup>57</sup> 421 (BLOSUM30). A maximum likelihood (ML) phylogeny was calculated in IQTree<sup>58</sup> with the 422 423 TEST option for best model selection and 100 bootstrap replicates. Metagenomes containing 424 one or several contigs coding for an McrA homologue that was only distantly related to 425 know lineages or belonged to undersampled lineages were downloaded from the IMG database. These metagenomes were assembled with MetaSPAdes<sup>59</sup>, IDBA-UD<sup>60</sup> and Newbler 426 427 (Roche) (see Supplementary Table 4 for details). The contigs were binned with ESOM,

MetaBAT<sup>61</sup>, ABAWACA 1.07 (http://ggkbase.berkeley.edu/), MaxBin 2.0<sup>62</sup> and CONCOT<sup>63</sup> 428 429 Table 4). An in-house pipeline (Let-it-bin, (Supplementary 430 https://github.com/QuentinLetourneur/Let-it-bin) was used for read trimming, assembly, and contig binning. Two of the MAGs were refined using DAS Tool<sup>64</sup>. Completeness and 431 contamination of the assembled MAGs were estimated with CheckM<sup>65</sup>. 432

## 434 *Phylogenomic analyses*

433

435 A reference archaeal phylogeny was built from a concatenation of 40 phylogenetic markers corresponding to the 36 proteins of the Phylosift dataset<sup>66</sup>, plus the alpha and beta subunits 436 437 of the RNA polymerase and two universal ribosomal proteins (L30, S4) (Supplementary Table 438 5). We used a subset of the genomes available for each order/class/phylum level lineages 439 (Supplementary Table 6) to minimize biased associated with uneven distribution of taxa 440 among them (e.g. >100 taxa in Halobacteriales vs. 3 taxa in Methanocellales). The 147 441 genomes were chosen because they were the most complete and the most distant to each 442 other within each lineage. Two phylogenies were built from a concatenation of McrABG and 443 of six co-localized markers (m4 to m9) specific to genomes encoding an MCR/MCR-like 444 complex. Sequences used for these trees were searched by HMM in the ten MAGs obtained 445 in this study and in genomes present in the NCBI or IMG-databases, aligned with Mafft<sup>56</sup> (mafft-linsi), trimmed with BMGE<sup>57</sup> (BLOSUM30) and concatenated with an in-house script. 446 Before concatenation, the genes of the two datasets (McrABG and m4 to m9) were tested 447 for congruence using the Internode Certainty (IC)<sup>67</sup> test in RaxML<sup>68</sup>. Maximum likelihood 448 phylogenies for each gene and blind concatenations were calculated in IQTree<sup>58</sup> with the 449 TEST option for best model selection and 100 bootstrap replicates. Sequences causing strong 450 451 incongruences (with a bootstrap>=80%) at high taxonomic ranks (order to phylum as 452 applicable) were removed, and the procedure was repeated until no further incongruence was found. Bayesian phylogenies were constructed in PhyloBayes<sup>69</sup> under the CAT+GTR+F4 453 454 model. Four independent Markov chain Monte Carlo chains were run until convergence and checked by sampling ever two cycles with a 25% burn-in. Support at nodes was evaluated by 455 posterior probability values. ML phylogenies were constructed in IQ-TREE<sup>58</sup> under the 456 457 LG+C60 model.

458

# 459 *Metabolic prediction*

Gene prediction was performed using Prodigal<sup>70</sup>. All metabolic genes were identified using 460 461 hidden Markov models (HMMs) searches with PFAM, TIGR and custom HMM profiles. Annotation of proteins displayed in Supplementary Table 1 were improved by inspecting the 462 genomic context of the metabolic genes using RAST<sup>71</sup> and SyntTax<sup>72</sup> (http://archaea.u-463 psud.fr/synttax/), by phylogenetic analyses including the sequences of characterized 464 enzymes and by identifying their conserved domains using CD-search batch<sup>73</sup> 465 466 (https://www.ncbi.nlm.nih.gov/Structure/bwrpsb/bwrpsb.cgi). Genomic context was also 467 inspected to identify conserved patterns among multiple genomes. Identification of energy conservation systems was performed with MacSyFinder<sup>74</sup>, by defining specific and sensitive 468 469 models for each system followed by manual curation.

470

471

## 472 Data availability

473 MAG sequences are available in the BioProject PRJNA472146 and Biosamples 474 SAMN10387997, SAMN10390728, SAMN10390732, SAMN10390733, SAMN10390735,

- 475 SAMN10390736, SAMN10390737, SAMN10390738, SAMN10390739. NM2 sequences
- 476 corresponding to markers reported in Table 2 are deposited under MK202738 to MK202758.
- 477 The data that support the findings of this study are available from the corresponding author
- 478 upon request.

#### 683 Acknowledgements

684

685 We thank Rudolf Thauer for feedback on an earlier version of the manuscript. G.B. 686 acknowledges support from the Institut Pasteur through a Roux-Cantarini fellowship. P.S.A. 687 is supported by a PhD fellowship from Paris Diderot University and by funds from the PhD 688 Program "Frontières du Vivant (FdV)-Programme Bettencourt". S.G. acknowledges funding 689 from the French National Agency for Research Grant ArchEvol (ANR-16-CE02-0005-01). This 690 work used the computational and storage services (TARS cluster) provided by the IT 691 department at Institut Pasteur, Paris. S.J.H. acknowledges support from the US Department 692 of Energy (DOE) JGI supported by the Office of Science of US DOE Contract DE-AC02-693 05CH11231, the Natural Sciences and Engineering Research Council (NSERC) of Canada, 694 Genome British Columbia, Genome Canada, Canada Foundation for Innovation (CFI), and the 695 Tula Foundation. I.N.S.G. and V.M.O. are grateful to São Paulo Research Foundation - FAPESP 696 (process numbers 2011/14501-6 and 2013/20436-8) and Petrobras for financial support and 697 to Dr. Neil Gray and Dr. Ian Head from the School of Civil Engineering and Geosciences at 698 Newcastle University for lab facilities. W-J.L. was supported by Key Projects of Ministry of 699 Science and Technology (MOST) (Nos. 2013DFA31980, 2015FY110100). G.M. was supported 700 by the ERC Advanced Grant PARASOL (No. 322551). L.J.M. appreciates funding from the 701 NASA Postdoctoral Program through the NASA Astrobiology Institute and W.P.I. was 702 supported by the Montana Agricultural Experiment Station (Project 911300).

#### 705 **Author contributions**

706

707 G.B. and S.G. conceived the study. L.J.M., L-X.C., I.N.S.-G., C.M.K.S., G.L.A., W.-J.L., S.J. H., 708 G.M., V.M.d.O., W.P.I., and J.F.B. sequenced and assembled the metagenomes. G.B. 709 screened the IMG database for McrA and identified these metagenomes. Q. L., A. G. and G. 710 B. developed the pipeline Let-it-bin. G.B. performed the contig binning of NM1a, NM1b, 711 NM2, NM3, NM4, Verst-YHS, and Mnatro-ASL MAGs. L-X.C. carried out the contig binning of 712 ANME-1-THS MAG and C.M.K.S. those of GoM-Arc1-GOS and ANME-2c MAGs. G.B. inferred 713 the metabolism associated to each MAG and performed all phylogenetic analyses. P.A. 714 performed the congruence tests. G.B. and S.G. wrote the manuscript. All authors read and

- 715 commented on the manuscript.

# 729 Figure legends

730

731 Figure 1: Placement of nine MAGs described in this study in the reference phylogeny of 732 Archaea. NM2 was not included due to low completeness. Bayesian phylogeny (PhyloBayes, 733 CAT+GTR+ T4) based on concatenation of 40 conserved phylogenetic markers (8,564 amino 734 acid positions) and 156 genomes/MAGs (see Supplementary Table 5 and Supplementary 735 Table 6 for detail). Node supports refer to posterior probabilities, and for reasons of 736 readability only values above 0.8 are shown. The tree is rooted according to Raymann et 737 al.<sup>52</sup>. The scale bar represents the average number of substitutions per site. Black arrows 738 point to the 9 obtained MAGs and accolated pie charts indicate their estimated 739 completeness. Colors indicate that genomes of these lineages encode an MCR/MCR-like 740 complex, Class I/II methanogens are in green, methyl-dependent hydrogenotrophic lineages 741 are in red, methanotrophs are in orange (some being within Class II), potential or validated 742 shot-chain alkane users are in in blue. NM1 could also have a methane metabolism (see text 743 for discussion).

744

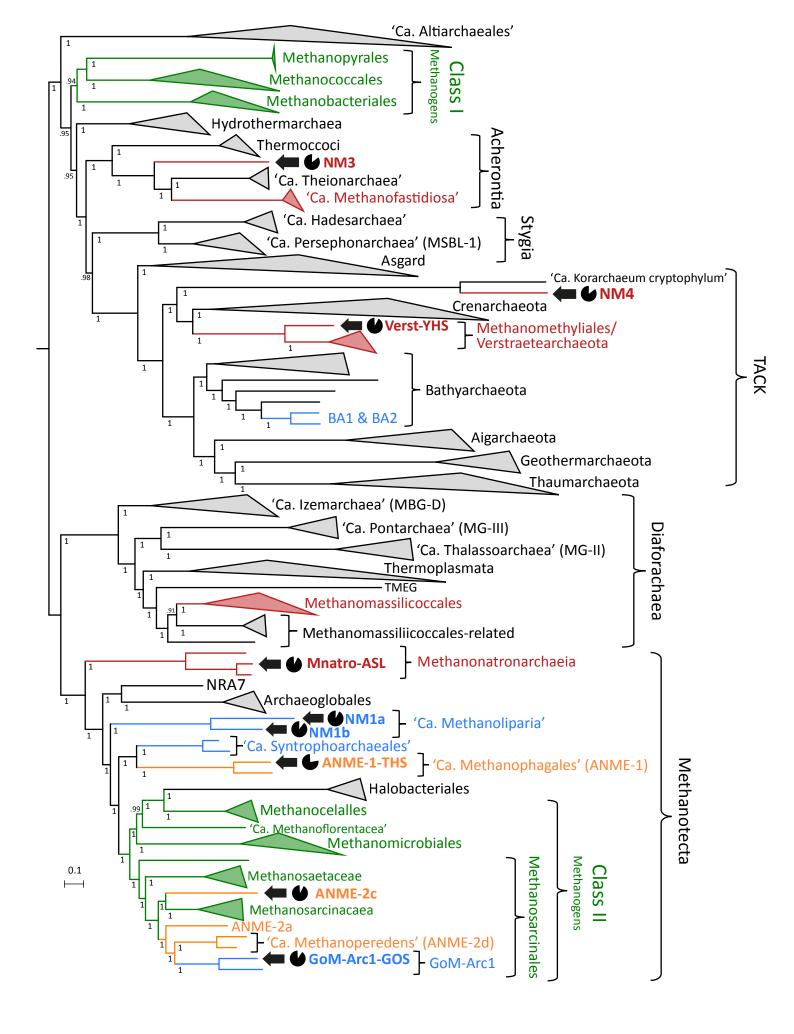

Figure 2: Phylogeny of the MCR/MCR-like complex and conservation of important positions 745 746 in the catalytic site. A) Unrooted Bayesian phylogeny (CAT+GTR+F4) based on a 747 concatenation of McrABG/McrABG-like subunits (1,187 amino acid positions) from 109 748 genomes/MAGs (see Supplementary Table 6 for details). Node supports refer to posterior 749 probabilities, and for reasons of readability only values above 0.8 are shown. The scale bar 750 represents the average number of substitutions per site. The color code is similar to that in 751 Fig. 1 with the exception of NM1 which have both an MCR-like (in blue) and a canonical MCR 752 (in purple) (see text for discussion). B) Conservation of 17 residues previously described to 753 interact with CoM, CoB, F<sub>430</sub> cofactors, making part of the substrate cavity wall, or having post-translational modifications<sup>27,47,75</sup>. Replacement of conserved amino acids associated to 754 755 a negative value in the Blosum45 matrix are indicated by white on black background, those 756 with a null or positive value in the Blosum45 matrix are in bold, "." indicate conserved 757 positions and "-" indicate missing positions in the sequence due to sequencing 758 incompleteness. 759

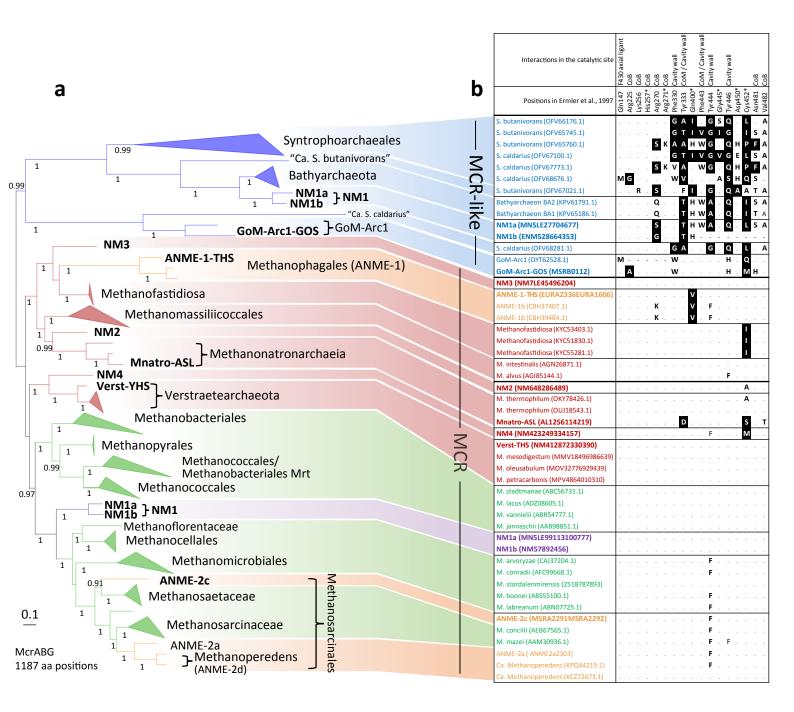

760 Figure 3: Predicted methane and short-chain alkane metabolism of the MAGs described in 761 this study, with the exception of NM1, which is presented in Fig. 4, and NM2, which has a 762 low completeness. Colored arrows correspond to reactions modifying or transferring the C1 763 carbon group of the substrate. Details on the annotation of the enzymes are presented in 764 Supplementary Table 1. MFR, methanofuran; H<sub>4</sub>MPT, tetrahydromethanopterin; Fd, 765 ferredoxin; F<sub>420</sub>, coenzyme F<sub>420</sub>; LCFA, Long Chain Fatty Acids; MQ, menaquinone; Mp, 766 methanophenazine; Mhc, c-type multiheme cytochromes; DIET, Direct Interspecies Electron 767 Transfer. Grey color indicates the absence of the enzyme, complex, reaction or compound. Comparisons of with other methane-cycling or short-chain alkane oxidizers, which are
discussed in the text, are presented in Supplementary Figs 1 and 3. The percentages
between brackets indicate the estimated completeness of the corresponding MAGs.

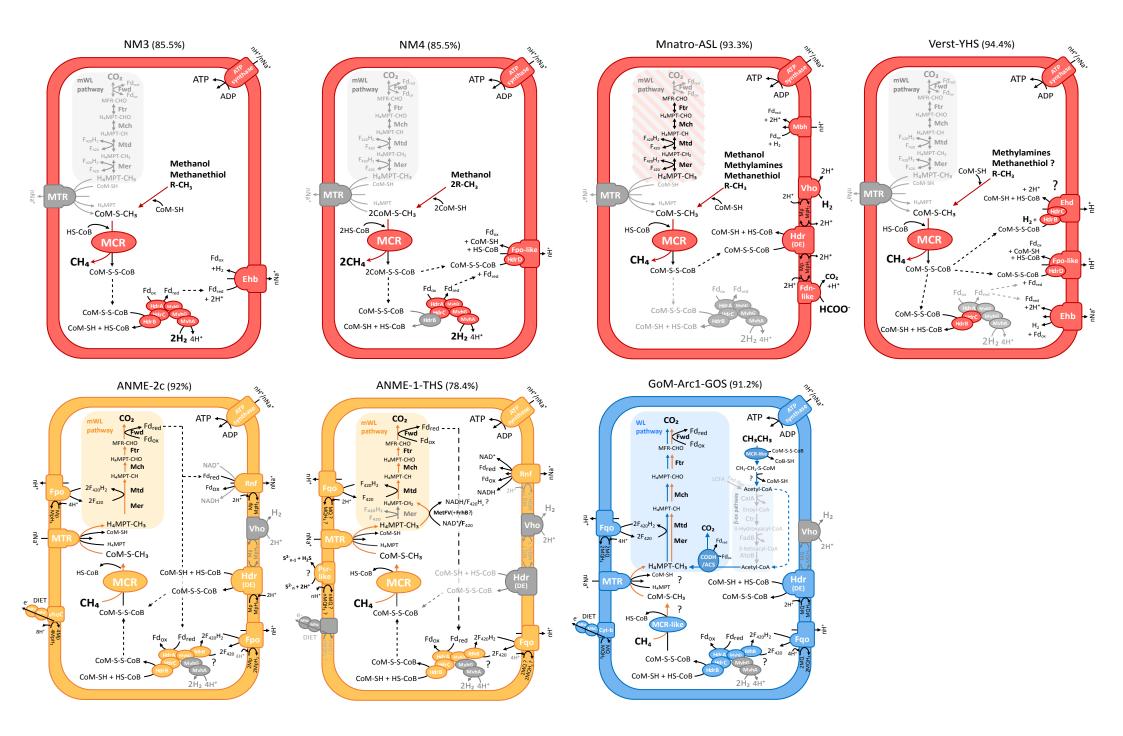

771

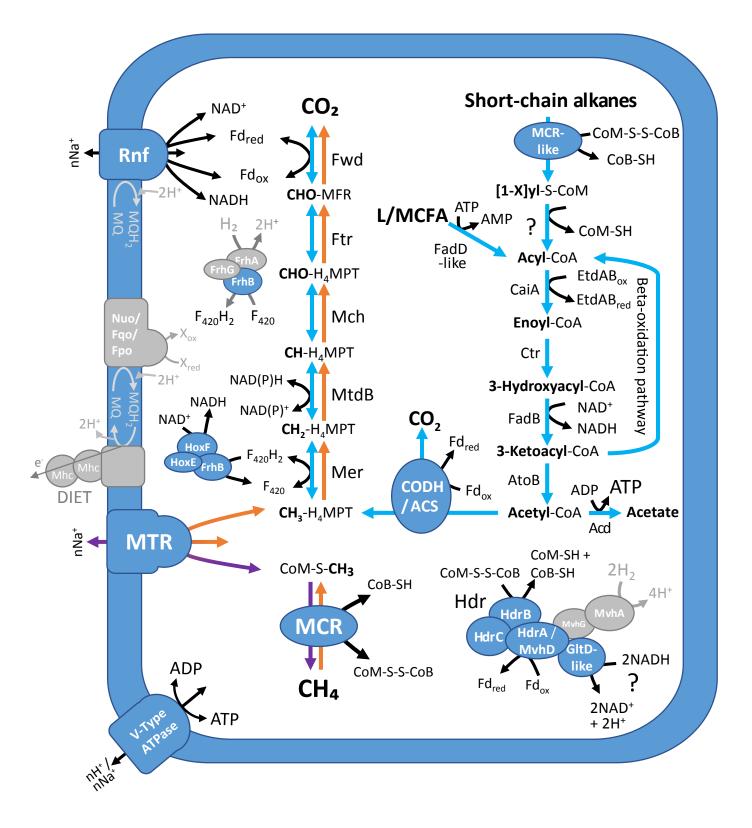

772 Figure 4: Predicted methane, short-chain alkane and long/medium-chain fatty acid 773 metabolism of the two MAGs NM1a ("Ca. Methanoliparum thermophilum" completeness of 774 92.5%) and NM1b ("Ca. Methanolliviera hydrocarbonicum" completeness of 90.2%) 775 belonging to the candidate class "Ca. Methanoliparia". Colored arrows correspond to 776 reactions present in both MAGs which modify or transfer the carbon group(s) of the 777 substrate. Predicted possible metabolisms are the utilisation of short-chain alkanes and 778 long/medium-chain fatty acids (L/MCFA) (blue), methanotrophy (orange) and 779 methanogenesis from short-chain alkanes or L/MCFA (purple). Details on the annotation of 780 the enzymes are provided in Supplementary Table 1. MFR, methanofuran; H<sub>4</sub>MPT, 781 tetrahydromethanopterin; Fd, ferredoxin;  $F_{420}$ , coenzyme  $F_{420}$ ; L/MCFA, Long/medium chain 782 fatty acids; MQ, menaquinone; Mhc, c-type multiheme cytochromes; DIET, Direct 783 Interspecies Electron Transfer. Grey color indicates the absence of the corresponding 784 enzyme, complex, reaction or compound in both MAGs.

785

The numbers in the cells colored in red/green indicate the proportion of genomes of one lineage that have a given marker (all = 1, none = 0). It is possible that some of the markers are present in the missing regions of the incomplete MAGs/genomes. For gene essentiality in Methanococcus maripaludis S2: predicted essential genes (Essentiality index  $\leq$  2) are highlighted in grey60. "m1", "m2", etc means "marker 1", "marker 2" etc; Msar, Methanosarcinales; AOM, Anaerobic Oxidation of Methane; SCAO, short-chain alkane oxidation; CH<sub>3</sub>-dep hydro, methyl-dependent hydrogenotrophic methanogenesis; MCR, methyl-coenzyme M reductase complex; MTR, N5-Methyltetrahydromethanopterin: coenzyme M methyltransferase complex; PTM, involved in post-translational modification of MCR are sed GoM-Arc1 genomes. \*NM1 MAGs encode for a SCAO metabolism and possibly for methanogenesis or methanotrophy. <sup>5</sup>Metabolic classification relying only on genomic predictions. The numbering and ordering of the marker was chosen to reflect their occurrence in methanogens, methanotrophy and short-chain alkane exidizers (i.e. from the most occurrent to the less occurrent) with few modifications in the order to gather markers involved in same functions or being part of same enzymatic complexes.
