16 ABSTRACT

Leptospirosis is an emerging disease with an annual occurrence of over 1 million human 17 cases worldwide. Pathogenic Leptospira are maintained in zoonotic cycles involving a diverse 18 array of mammals with the capacity to survive outside the host in aquatic environments. Survival 19 in the diverse environments encountered by Leptospira likely requires various adaptive 20 21 mechanisms. Little is known about Leptospira outer membrane modification systems, which 22 may contribute to the capacity of these bacteria to successfully inhabit and colonize diverse environments and animal hosts. Leptospira encode two genes annotated as UDP-3-O-[3-23 hydroxymyristoyl] glucosamine N-acyltransferases (la0512 and la4326, lpxD1 and lpxD2), that 24 in other bacteria are involved in the early steps of lipid A biosynthesis, the membrane lipid 25 anchor of lipopolysaccharide. Inactivation of only one of these genes, la0512/lpxD1, imparted 26 sensitivity to host physiological temperature (37°C) and rendered the bacteria avirulent in an 27 28 animal infection model. Polymyxin B sensitivity assays revealed compromised outer membrane integrity in the *lpxD1* mutant at host physiological temperature, but structural analysis of lipid A 29 in this mutant revealed only minor changes in the lipid A moiety compared to that found in the 30 wild type strain. In accord, an *in-trans* complementation restored phenotypes to a level 31 comparable to the wild type strain. These results suggest that the gene annotated as *lpxD1* in *L*. 32 interrogans plays an important role in temperature adaptation and virulence in the animal 33 infection model. 34

35 INTRODUCTION

Leptospira are spirochete bacteria encompassing saprophytic and pathogenic species and are considered to be the most widespread zoonotic bacteria world-wide (1). *Leptospira* are the etiological agents of the disease leptospirosis which in severe manifestation leads to hemorrhage

in the lungs, meningitis, liver and/or kidney failure (1). Leptospirosis is an emerging disease and 39 the worldwide annual occurrence is estimated to be over 1 million human cases with a 5-20% 40 mortality rate (2, 3). Leptospira cannot breach the host epidermal lining and transmission 41 requires direct contact of the bacteria with cuts or abrasions in the skin (4, 5). Rats and other 42 rodent species serve as reservoir hosts for Leptospira, which colonize the urinary system of these 43 animals (6). Leptospira are shed back into the environment through the urine of reservoir hosts 44 and can persist in fresh water and soil until direct contact with an animal recommences an 45 infection cycle (7, 8). 46

A prominent Leptospira feature is the ability to proliferate in significantly different 47 environmental conditions. Other Gram-negative bacterial pathogens with this unique ability 48 include species of the genera Escherichia (9), Salmonella (10), Yersinia (11), Vibrio (12) and 49 Pseudomonas (13). The capacity of bacteria to adapt to disparate environments is likely imparted 50 51 by numerous evolved strategies that likely include modification of outer membrane macromolecules (14-17). Outer membrane fluidity and permeability is partly modulated by 52 hydrophobic acyl chains of lipid A regions of lipopolysaccharide (LPS) (18). Environmental 53 fluctuations such as temperature alter outer membrane fluidity (19) and bacteria counter by 54 altering acyl chain lengths, the number of acyl groups added to the lipid A moiety and/or the 55 modification of acyl chain saturation, to maintain outer membrane integrity (20-22). 56

57 Measurements of the toxicity of *L. interrogans* LPS suggest that while the molecule is 58 less toxic than *Escherichia coli* LPS (23), *L. interrogans* LPS is toxic to a variety of cells (24) 59 and tissues encountered by the pathogen during the course of animal infection (25). *L.* 60 *interrogans* LPS is also an immunodominant molecule (26, 27) and unique in that it is 61 recognized by TLR2 and not TLR4 in human cells (LPS from the majority of other Gram negative bacteria is recognized by TLR4) (28). Pathogenic *Leptospira* demonstrate more abundant and longer LPS compared to the saprophyte *L. biflexa* (29) and mutations affecting the native biosynthesis of LPS affect both virulence in hamsters (30) and colonization of target organs in the mouse model (31).

Acylation of lipid A has been shown to be crucial for the fitness of bacteria outside and 66 within the host (15, 20, 21). The L. interrogans genome encodes homologs of the enzymes 67 required for lipid A biosynthesis and this biosynthetic process has been previously proposed in L. 68 (32). of L. interrogans Structural analyses interrogans serovars 69 Pomona and Icterohaemorrhagiae (strain Verdun) lipid A have been performed, revealing identical structures 70 composed of a 2,3-diamino-2,3-dideoxy-D-glucopyranose disaccharide with four amide linked 71 acyl groups composed of R-3-hydroxylaurate at positions 3 and 3' and R-3-hydroxypalmitate at 72 positions 2 and 2' (32). Two secondary unsaturated acyl chains are ester linked to the 2' and 3' 73 74 hydroxy-acyl groups to produce hexa-acylated lipid A as the major species (32). Previous structural analysis of L. interrogans lipid A suggested that the C2 and C2' amine groups are 75 acylated with 16 carbon length hydroxy-acyl groups (32), which would suggest that the L. 76 interrogans LpxD enzyme is selective for 16 carbon 3-hydroxy-acyl chains. The L. interrogans 77 serovar Manilae examined in this report, have two genes (la0512 and la4326) that display 78 homology to *lpxD* in other Gram-negative bacteria. The present study aimed to characterize 79 80 pathogenic L. interrogans serovar Manilae lpxD homologs in the context of outer membrane integrity conferring temperature adaptation and virulence in an animal infection model. 81

82 MATERIALS AND METHODS

83 Leptospira strains and culturing

Leptospira interrogans serovar Manilae strain L495, the $la0512^{-}$ ($lpxD1^{-}$) and la4326⁻ ($lpxD2^{-}$) mutants, and $la0512^{-}$ mutant complemented with la0512 ($lpxD1^{-}$ /+) were maintained in EMJH growth medium at 30°C, with agitation.

87 Insertion mutagenesis and complementation.

Insertion inactivation in *L. interrogans* has been previously described (33). The insertion 88 sites within la0512 (*lpxD1⁻*) and la04326 (*lpxD2⁻*) were identified by semi-random PCR 89 followed by DNA sequencing. The insertion was further confirmed via PCR using primers 90 flanking the insertion sites. For complementation, $lpxDl^{-}$ was PCR amplified using primers 91 (5'-GGGAATTCCATATGAAAGCCAAAAATTTAGCG-3') 92 *lpxD1*F and *lpxD1*R (5'-CGG<u>CTCGAG</u>ATCCAATTCAACCTG -3'), which incorporated restriction digestion sites for 93 NdeI and XhoI, respectively (underlined bases). The *lpxD1* coding sequence was then digested 94 with NdeI and XhoHI, purified, and inserted into the same restriction sites of pCRPromFlgB (34) 95 to generate a transcriptional fusion between the gene and the *Borrelia burgdorferi flgB* promoter. 96 DNA fragments containing the transcriptional fusions were released by KpnI and XhoI 97 98 digestions and cloned into the corresponding sites of pAL614 (generous gift from Gerald Murray, Monash University). The *lpxD1* complementation construct was introduced by 99 conjugation in Manilae $lpxD1^{-}$ strain as previously described (35) and complementation of the 100 *lpxD1*⁻ strain was confirmed by using primers that PCR amplified a region of the spectinomycin 101 resistance cassette and primers *lpxD1*F and *lpxD1*R, using genomic DNA as template. 102

103 Growth rate measurements, susceptibility assays and morphology determination

To determine whether mutant, complemented and wild type Leptospira strains were 104 affected in growth in vitro, bacteria were enumerated using a Petroff-Hausser Counting Chamber 105 (Hausser Scientific Company, Horsham, Pennsylvania, USA) under dark field microscopy. A 106 total of 2000 of each strain was used to inoculate 9 ml EMJH, in triplicate. Growth was 107 monitored on a daily basis at 30°C and 37°C, by counting bacteria using a Petroff-Hausser 108 counting chamber under dark field microscopy. For enumerating strains on a daily basis, equal 109 volume aliquots of samples were pooled and counted in duplicate. Growth experiments were 110 performed 4 times with similar trends, a representative result from a single experiment is 111 displayed in Fig. 1. 112

Temperature sensitivity was measured by adding 200 µl of bacteria at a concentration of 113 $5x10^{6}$ bacteria/ml in EMJH to 96 well culture plates, in triplicate. Plates were sealed to prevent 114 evaporation and incubated at 23°C, 30°C or 37°C for 72 h. To measure cell viability, bacterial 115 116 cultures were transferred to a single 96 well culture plate and 20 µl of AlamarBlue (Life Technologies SAS, Saint Aubin, Île-de-France, France) was added to bacteria and plates 117 incubated for 24 h at 30°C. Temperature sensitivity experiments were performed twice with 118 similar results and a representative result from a single experiment is displayed in Fig. 1. For 119 polymyxin B (Sigma, Saint Louis, Missouri, USA) sensitivity assays experiments were 120 performed as described for the temperature sensitivity assays with the following modifications. 121 122 Polymyxin B was added to 96 well plates in the range of 20 μ g/ml – 0.02 μ g/ml, using 2 fold serial dilutions. Bacteria were added to a final volume of 200 µl and a final concentration of 123 5x10⁵ bacteria/ml. Plates were sealed to prevent evaporation and incubated at 30°C or 37°C for 124 24 h, and 20 µl of AlamarBlue was subsequently added per well and plates were sealed and 125 incubated at 30°C for 48 h to measure cell viability. For these experiments the starting bacterial 126

127 concentration was 5×10^5 (as opposed to 5×10^6 for temperature sensitivity assays above) to ensure 128 $lpxD1^-$ viability at 37°C as the viability of this mutant rapidly declines with increasing bacterial 129 concentration at 37°C. Polymyxin B experiments were performed two times with comparable 130 results and a representative result from a single experiment is displayed in Fig. 2.

Morphological changes were measured by first growing bacterial strains at 23°C, 30°C or 37°C to a density of 5x10⁶ bacteria/ml, in triplicate. Ten microliter aliquots of bacteria were viewed by dark field microscopy at 200x magnification and images captured using Olympus CellSens Dimensions version 1.7.1 (Olympus, Rungis, Île-de-France, France). Twenty bacteria were measured length-wise (using the CellSens Dimensions version 1.7.1 measuring tool) per replicate for a total of 60 bacteria per strain, from each temperature. Statistical analysis was performed using two-way ANOVA.

138 **RNA extraction and RT-qPCR**

Leptospira strains were cultured in triplicate at 30°C in EMJH to a density of 1×10^8 139 bacteria/ml and a total of 10¹⁰ of each strain from each replicate was used for RNA extraction 140 and RT-qPCR, as previously described (35-38). The following modifications were implemented 141 for RT-qPCR; the primers used to quantify respective genes included lpxD1f 5'-142 ATCCGAACGTTGTCATTGAA and *lpxD1*r 5'-GATCACCGTATTCGCATGAA to quantify 143 lpxD1⁻ transcripts and lpxD2⁻f 5'-TCATCCTTCTGCAAAGTTGG and lpxD2⁻r 5'-144 AACGCCGTCTTCCAAATAAG to quantify *lpxD2* transcripts. Statistical analysis was 145 performed using both biological replicates (n=3) and RT-qPCR technical replicates (n=3) using 146 unpaired Student's *t*-test, comparing strains individually. 147

148 LPS purification and immunoblot analyses

Leptospira strains were cultured at 37°C in EMJH to a density of 1×10^7 bacteria/ml and 149 harvested via centrifugation at 9,000 xg for 10 min to obtain a total of 10^{10} cells of each strain. 150 The LPS was purified as previously described (30) with the following modifications. 151 Immediately after harvesting, Leptospira pellets were resuspended in 1x PBS-0.1% SDS to a 152 concentration of 10⁹ bacteria/ml and sonicated for 45 sec at 20 W. Proteinase K was added to a 153 final concentration of 30 µg/ml and samples were incubated at room temperature 24 h on a 154 RotoFlex Tube Rotator (Argos Technologies, Elgin, Illinois, USA). Samples were subsequently 155 mixed with 4x Laemmli protein sample buffer (Bio-Rad, Marnes-la-Coquette, Île-de-France, 156 France) and used for SDS-PAGE, Silver Staining and immunoblot analysis using an equivalent 157 volume of 1×10^7 bacteria per lane. Immunoblots were performed using *Leptospira interrogans* 158 serovar Manilae strain L495 positive guinea pig sera which was obtained as previously described 159 (39), at a 1:100 dilution in 1x PBS/5%(w/v) skim milk/0.1% Tween-20 (PBSMT). Guinea pig 160 sera were detected with horse radish peroxidase-conjugated goat anti-guinea pig 161 immunoglobulins as previously described (39). These experiments were performed 3 times with 162 similar results and the result from a single experiment is displayed in Fig. S1. 163

164 Isolation and MALDI-MS analysis of lipid A

Leptospira strains were grown in EMJH media at 30° C or 37° C to a density of 3×10^{7} bacteria/ml and a total of 3×10^{10} of each strain from each temperature was used for lipid A isolation. Lipid A isolation and mass spectrometry were performed as previously described (40) with the following modifications. Cells were harvested by centrifugation, washed with PBS, and stored at -20°C until lipid A extraction. Previously described modifications to the methods of Caroff and Raetz were used to chemically isolate lipopolysaccharide, where isolated material was treated by boiling mild-acid hydrolysis for 45 minutes to liberate lipid A from attached polysaccharide (40-42). The method of Bligh and Dyer was used to extract lipid A after mildacid hydrolysis (43). Isolated lipid A was dried under nitrogen and stored at -20°C until further
use.

Lipid A extracts were further purified over a diethylaminoethyl (DEAE) column to 175 improve the quality of spectra obtained by MALDI-MS. Briefly, dried lipid A was suspended in 176 2:3:1 v/v chlorofom:methanol:water (C:M:W) and applied to a 1.5 ml pre-equilibrated DEAE 177 column. The column was washed with 20 column volumes of 2:3:1 C:M:W, and lipid A species 178 were eluted stepwise with 5 column volumes of 2:3:1 C:M: ammonium acetate at 60 mM, 120 179 mM, 240 mM, or 480 mM ammonium acetate. An additional two-phase Bligh-Dyer extraction 180 181 was performed on the eluate to remove ammonium acetate. Isolated lipid A was dried under nitrogen and stored in small conical glass vials at -20°C until MALDI-MS analysis. Lipid A was 182 resuspended in 25 µl chloroform-methanol (4:1). An empirically determined amount of lipid A, 183 184 varied per sample, was mixed with 0.5 μ l of matrix (saturated 6-aza-2-thiothymine in 50%) acetonitrile: saturated tribasic ammonium citrate (20:1, v/v)) and spotted on a 100 well MALDI 185 plate. The AB SCIEX Voyager was used to collect MALDI-MS-TOF data in the negative 186 reflectron mode. Consistent with previous reports in L. interrogans, m/z peaks corresponding to 187 lipid A species were present in most of the 60 mM ammonium acetate fraction spectra (32). The 188 proposed absence of the 4'-phosphate group and a methylated 1-phosphate contribute to the early 189 elution of lipid A from L. interrogans (32). No peaks corresponding to lipid A were observed in 190 the later 120, 240, 480 mM ammonium acetate fractions. Spectra obtained represent the average 191 of >300 shots. 192

193 Gerbil infection and bacterial burden in target organs

An initial virulence experiment was performed in gerbils with Manilae wt strain and the mutant strains $lpxD1^-$ and $lpxD2^-$. For these experiments, groups of 4 gerbils were challenged intraperitoneally with each of the aforementioned strains using 10⁴ bacteria per animal. Animals were monitored for 20 days and euthanized, when possible, to minimize animal suffering. A second infection experiment was performed as described above with the following modification: complemented $lpxD1^-$ strain $(lpxD1^{-/+})$ was used in place of strain $lpxD2^-$ and infections were performed at doses of 10⁴ and 10⁶ bacteria per animal, in groups of 4 gerbils per bacterial dose.

Leptospira burden in kidneys and liver were determined by qPCR, as previously described (35, 44), with the following modifications. *Leptospira* strains Manilae wild type, $lpxDI^-$ and $lpxDI^{-/+}$ were injected intraperitoneally into groups of 4 gerbils (10⁴ bacteria per animal). Five days post injection of bacteria, animals were euthanized and kidneys and liver from each animal was harvested for culturing in EMJH and for qPCR. Calculations of bacterial burden were performed to obtain the number of bacteria per 100 mg organ. F test to compare variance (p < 0.0064) was used to compare bacterial burden in target organs.

208 Ethics statement

The protocols for the animal experiments were prepared according to the guidelines of the Animal Care and Use Committee of Institut Pasteur of Paris and the present study was approved by this committee (N° CETEA 2013-0019).

212 **RESULTS**

213 *lpxD1* inactivation reduces *L. interrogans* fitness at host physiological temperature

LpxD enzymes have been shown to contribute to bacterial temperature adaptation via 214 modification of acyl chain length of the lipid A region of lipopolysaccharide (15). To determine 215 whether *lpxD* genes contained similar functionality in *Leptospira*, strains with *Himar1* 216 transposon insertions in the genes la0512 and la4326 ($lpxD1^{-}$ and $lpxD2^{-}$, respectively) were 217 obtained from a previously generated library of transposon insertion mutants (33, 45). In vitro 218 growth rates of mutant strains $lpxDl^{-}$ (la0512) and $lpxD2^{-}$ (la4326) were compared to parent 219 Manilae L495 strain (wt) at 30°C and 37°C (Fig. 1A and B). These experiments showed 220 comparable growth rates for both mutants and wt at 30°C, however, at 37°C reduced cell density 221 was observed in mutant $lpxDl^{-}$ relative to wt and mutant $lpxD2^{-}$ (Fig. 1B). To further test 222 mutant $lpxDl^{-}$ temperature susceptibility, mutant strains were cultured to a density of $5x10^{6}$ /ml 223 (approaching the approximate density at which point $lpxDl^{-}$ lost viability at 37°C) in growth 224 media and incubated at 23°C, 30°C and 37°C for 72 h. Following the 72 h incubation, bacterial 225 viability was measured via AlamarBlue viability assay which demonstrated that mutant *lpxD1* 226 was not viable at 37°C (Fig. 1C). 227

To validate these observations, mutant $lpxD1^{-}$ was complemented with the native lpxD1gene under the control of a constitutive promoter (technical limitations prevented complementation with native lpxD1 promoter). The resulting strain $(lpxD1^{-/+})$ displayed a surprisingly faster growth rate at 37°C and reached a higher density at both 30°C and 37°C when compared to the mutant and wt strains (Fig. 1A and B). Quantitative RT-PCR (RT-qPCR) was used to measure relative lpxD1 transcription in the respective strains, demonstrating a >2.5 fold increase in lpxD1 transcription in $lpxD1^{-/+}$ when compared to wt (supplemental Fig. S1).

235 Increased outer membrane permeability in mutant *lpxD1*⁻

Outer membrane integrity was assessed using polymyxin B assays conducted at 23°C, 30°C and 37°C and the viability of the bacteria were determined using AlamarBlue assays (Fig. 2A). Interestingly, mutant $lpxD2^-$ displayed a 2 fold higher resistance to polymyxin B and this resistance was independent of the tested temperatures (Fig. 2A). In contrast, mutant $lpxD1^$ exhibited a 2 fold higher sensitivity to polymyxin B at 37°C but not at 30°C or 23°C, when compared to the other strains (Fig. 2A). The wt and $lpxD1^{-/+}$ strains displayed comparable polymyxin B susceptibility (Fig. 2A).

Reduced outer membrane integrity can lead to osmotic stress resulting in reduced cell size (46). To assess whether strains displayed morphological differences, the cell lengths of the mutant, complement and wt strains were measured using dark field microscopy (supplemental Fig. S2). These analyses revealed that at 37°C the cell length of mutant $lpxD1^{-}$ was reduced by 16% (1.5 µm on average) when compared to the other strains (supplemental Fig. S2).

lpxD1 is required for leptospiral kidney and liver colonization and for fatal leptospirosis in gerbils

Immunoblot analysis using Leptospira positive sera and total LPS from mutant, 250 complement and wt strains grown at 37°C demonstrated reduced reactivity with LPS obtained 251 from mutant $lpxDl^{-}$ (Fig. 3), providing indirect evidence of lpxDl function in the host. To 252 253 ascertain whether *lpxD1* function was also required for survival of *Leptospira* in the host, mutants *lpxD1*, *lpxD2* and wt strain were used in virulence experiments in the gerbil infection 254 model (Fig. 4A). These experiment revealed that when animals were injected intraperitoneally 255 with 10^4 bacteria per gerbil, those infected with strain $lpxDI^-$ survived the 20 day infection 256 experiment (Fig. 4A), without visual signs of morbidity, whereas animals infected with *lpxD2*⁻ 257 and those with wt died by day 7. In separate experiments mutant $lpxDl^{-}$, complemented $lpxDl^{-+}$ 258

and wt strain were injected into the intraperitoneal cavity of gerbils at doses of 10^4 or 10^6 (Fig. 4B). Animals infected with strain $lpxD1^-$ at a dose of 10^4 and 10^6 per animal remained asymptomatic for the duration of the 20 day experiment whereas animals infected with wt or strain $lpxD1^{-/+}$ died at days 5 and 7 post infection, when injected with doses of 10^6 or 10^4 bacteria, respectively (Fig. 4B).

For analysis of bacterial burden in kidneys and liver, gerbils were injected 264 intraperitoneally with 10⁴ strain $lpxDI^{-}$, complement $lpxDI^{-/+}$ or wt strain and 5 days post 265 infection animals were sacrificed to obtain kidneys and livers for quantitative real-time PCR 266 (qPCR) and for *in vitro* culturing. Quantitative real-time PCR led to the detection of *lpxD1*⁻ 267 DNA in the kidneys and livers at an approximately ten fold lower quantity compared to wt (Fig. 268 4C). To distinguish between viable bacteria that had established colonization and those that 269 reached the target organs but that died shortly after, organs were also used for *in vitro* culturing. 270 The wt and $lpxD1^{-/+}$ strains were culture positive in all of the kidneys and livers tested but strain 271 *lpxD1*⁻ was negative for growth (data not shown). 272

273 Structural analyses of Leptospira lipid A

MALDI-MS analysis of lipid A species isolated from L. interrogans serovar Manilae 274 produced data that is similar to previously published reports on serovars Pomona and 275 276 Icterohaemorrhagiae (32). The previously proposed structure of L. interrogans lipid A is 277 hexaacylated, contains a methylated 1-phosphate and lacks a 4'-phosphate group (33) (Fig. 5). Consistent with this structure, fractionation of L. interrogans server Manilae lipid A using 278 anion exchange chromatography (DEAE) revealed early elution (60 mM ammonium acetate) of 279 lipid A species consistent with a net decrease in anionic character due to the absence of a 4' 280 phosphate group and the presence of a methylated 1-phosphate group. Unmodified hexa-acylated 281

bis-phosphorylated lipid A typically elutes in the 240 mM ammonium acetate fraction during DEAE fractionation. Unique to our analysis of serovar Manilae is an overall reduction in the observed m/z relative to serovars Pomona and Icterohaemorrhagiae by m/z 2 (Fig. 6A; 37°C) or 4 (Fig. 7A; 30°C), consistent with the incorporation of fatty acids with 1 or 2 more degrees of unsaturation (Fig. 5). The location of the unsaturated bond cannot be determined by MALDI-MS.

In all spectra the predominant, putative lipid A species peak is flanked by less intense 288 peaks at m/z -28 or +28 (Fig. 6 and Fig. 7), consistent with a lipid A species containing acyl 289 chains that vary in length by 2 less or 2 more carbons, respectively. These peaks are also 290 observable in MS data from previously characterized serovars Pomona and Icterohaemorrhagiae 291 (32). In serovar Manilae an even shorter acyl-chain containing lipid A is present in $lpxD1^{-}$, 292 which varies from the predominant peak by m/z -56, corresponding to a reduction in acyl chain 293 294 length by 4 carbons (Fig. 6B and Fig. 7B). Complementation of the *lpxD1*⁻ mutant with a wild type copy of *lpxD1* resulted in the disappearance of this peak at either temperature (30°C or 295 37°C), resulting in a spectrum similar to wild-type (Fig. 6C and Fig. 7C). Analysis of lipid A 296 from *lpxD2*⁻ resulted in a spectra very similar to that obtained for the wild-type at 37°C (Fig. 297 6D). However, the MALDI/MS spectra obtained from lipid A purified from mutant lpxD2⁻ 298 grown at 30°C consistently produced a spectra lacking the major spectral peaks (Fig. 7D) at m/z299 1691, 1719 and 1747 observed in wild-type samples (Fig. 7A). 300

301 **DISCUSSION**

Phenotypic characterization of mutant and the complemented $lpxD1^{-/+}$ strains demonstrated that lpxD1 is required for optimal bacterial growth and survival at temperatures corresponding to that found within the host (37°C). Furthermore, temperature sensitivity of $lpxD1^{-}$ mutant at 37°C was at least partially a result of increased outer membrane permeability, as demonstrated by polymyxin B susceptibility assays. We did not assess bacterial growth at temperatures lower than 23°C, as *Leptospira* growth rate rapidly declines at lower temperatures *in vitro*. We cannot therefore exclude the importance of *lpxD2* for bacterial viability at lower temperatures. The use of two different LpxD enzymes for temperature adaptation has been previously demonstrated in the Gram-negative bacterial species *Francisella* (15).

Consistent with the requirement for *lpxD1* functionality at 37°C, comparative 311 immunoreactivity of whole LPS molecules from wt, mutant and complemented strains suggested 312 that *lpxD1* is functional during the infection process in animals. Furthermore, virulence 313 experiments in animals indicated that *lpxD1* was essential for the ability of *Leptospira* to 314 colonize target organs and to cause fatal disease in gerbils. The lack of *lpxD1* expression and 315 functionality in the *lpxD1*⁻ mutant likely rendered *Leptospira* inept in maintaining a stable outer 316 317 membrane for proper functioning of the bacteria at the elevated temperatures found within the host. Reduced fitness within the host due to increased outer membrane permeability was also 318 likely further compounded by increased susceptibility to host antimicrobial peptides. 319

MALDI-MS analysis of lipid A species from all Leptospira strains used in the present 320 study demonstrated a somewhat heterogeneous mixture with respect to degrees of unsaturation 321 and overall acyl chain length. The predominant species observed corresponds to the proposed 322 structure in Fig. 5. Spectra from $lpxDl^{-}$ mutant strain displayed an additional lower m/z peak 323 suggestive of a lipid A moiety with shortened acyl chain lengths. The appearance of the smaller 324 acyl-chain containing lipid A species in the *lpxD1*⁻ mutant might suggest that the protein product 325 of *lpxD2* (if indeed functional) has a more relaxed acyl chain substrate specificity than that of 326 *lpxD1*, allowing the incorporation of even smaller acyl chains into the final lipid A structure. 327

Comparison of the major lipid A species for *L. interrogans* serovar Manilae showed that at lower 328 temperatures the most predominant lipid A species at 30°C (m/z 1719.7) contained one more 329 degree of unsaturation relative to the predominant species at 37°C (m/z 1722.0). The 330 homeoviscous adaptation hypothesis for bacterial membranes predicts increased unsaturated 331 fatty acid content at low temperatures which promotes the necessary increase in fluidity, required 332 for optimal bacterial membrane functionality (22, 47). Direct biochemical characterization of 333 LpxD1 and LpxD2 will be required to determine the precise contribution of each enzyme to the 334 observed lipid A species in this study. It is also possible that changes in fatty-acid donor pools 335 (ratio of various acyl-ACPs) as a consequence of varying growth temperatures, or the activity of 336 secondary lipid A acyltransferases, LpxL or LpxM, might contribute to the observed changes in 337 lipid A acyl chain length/unsaturation. 338

The results of the present study are in agreement with previous theories on bacterial 339 340 mechanisms used for modulating outer membrane integrity for bacterial adaptation to new environments. Contrary to other bacteria, such as Yersinia and Neisseria, the total number of L. 341 interrogans lipid A acyl chains appeared to remain constant under the various temperatures 342 tested. In the case of L. interrogans, the effect(s) of acyl chain length and level of acyl chain 343 saturation on thermal acclimatization and virulence in the animal infection model remains 344 unclear. These results allow us to extrapolate that L. interrogans likely utilize lpxD1 function to 345 maintain outer membrane integrity when transmitted from niche inanimate environments, such as 346 soil and water, to the animal host. 347

348 ACKNOWLEDGEMENTS

The authors would like to thank Catherine Werts for discussions and critical reading of the manuscript. This work was funded by the FUI 14 (Fonds Unique Interministériel) 351 "COVALEPT" and BPIFrance. Azad Eshghi was funded by a Carnot grant of the "Institut

352 Carnot- Pasteur Maladies Infectieuses". Also acknowledged are NIH grants AI064184 and

491 FIGURE LEGENDS

Fig. 1. Inactivation of Leptospira lpxD1 results in temperature sensitive growth. Leptospira 492 parent wt, mutant lpxD1 ($lpxD1^{-}$) and lpxD2 ($lpxD2^{-}$), and complemented lpxD1 ($lpxD1^{-/+}$) 493 strains were used to compare temperature sensitivity. (A) Strains were cultured in triplicate at 494 495 30°C and cell density measured for each strain by pooling replicates and counting cells using Petroff-Hauser counting chambers under dark field microscopy, daily. (B) Strains were cultured 496 at 37°C and cell densities determined as for 30°C cultures. (C) Temperature sensitivity was also 497 determined by exposing strains at a density of 5×10^6 /ml to the indicated temperatures for 72 h. 498 Cell viability was subsequently measured using an alamarBlue assay where pink represents 499 viable cells, blue non-viable cells and intermediate between pink and blue represents reduced 500 viability 501

Fig. 2. Reduced outer membrane integrity in the $lpxD1^{-}$ mutant at 37°C. The relative outer membrane permeability of *Leptospira* parent wt, mutant lpxD1 ($lpxD1^{-}$) and lpxD2 ($lpxD2^{-}$), and complemented $lpxD1^{-}$ ($lpxD1^{-/+}$) strain was tested by measuring minimum inhibitory concentrations to the cationic compound polymyxin B. Bacteria were exposed to polymyxin B at the indicated concentration range (using two fold successive dilutions) for 72 h at the designated temperatures. Cell viability was measured using the alamarBlue assay, viable bacteria arerepresented in the pink wells and non-viable bacteria in blue wells.

Fig. 3. Inactivation of *lpxD1* results in lowered immunoreactivity to LPS. Crude LPS extracts of bacteria grown at 37°C were applied to SDS-PAGE and used in immunoblot experiments with sera from guinea pigs infected with wild type Manilae. (A) Silver stained SDS-PAGE of crude LPS from the indicated strains. (B) Immunoblot displaying IgG reactivity of *Leptospira* positive sera against crude LPS from indicated strains.

Fig. 4. Mutant *lpxD1⁻* does not colonize target organs in the gerbil infection model. 514 Leptospira parent wt, mutant lpxD1 (lpxD1⁻) and lpxD2 (lpxD2⁻), and complemented lpxD1 515 $(lpxDI^{-/+})$ strains were used to assess virulence in gerbils. (A) Groups of 4 gerbils were 516 inoculated with the indicated numbers of each strain, intraperitoneal and monitored for 20 days. 517 (B) Infection experiment were performed as described for panel A. (C) Groups of 4 gerbils were 518 inoculated intraperitoneal with 10^4 of each indicated strain per animal. Five days post 519 inoculation, animals were euthanized and livers and kidneys taken for qPCR and in vitro 520 culturing of bacteria in EMJH. ^aCulture positive from both liver and kidney, ^bNegative for 521 522 culture growth from liver and kidney.

Fig. 5. Proposed chemical structure of the major lipid A species from *L. interrogans.* Chemical representations of the predominant species of lipid A in serovars Pomona and Verdun, as proposed in a previous report (32), and serovar Manilae, the putative structure proposed in this report. The exact mass, and the monoisotopic mass (m/z) for MS in the negative mode are displayed. Fig. 6. MALDI-MS analysis of DEAE fractionated lipid A from *L. interrogans* serovar Manilae grown at 37°C. Lipid A isolated from each indicated strain was fractionated over a DEAE anion-exchange column. Mass spectra were obtained using the 60 mM ammonium acetate DEAE fraction for lipid A isolated from WT (A), $lpxD1^{-}$ (B), $lpxD1^{-/+}$ (C), and $lpxD2^{-}$ (D) strains of *L. interrogans* serovar Manilae. Each spectra is the average of >300 laser pulses. Based on relative % signal intensity, the most abundant m/z peak for each isotopic cluster is labeled.

534 Fig. 7. MALDI-MS analysis of DEAE fractionated lipid A from L. interrogans serovar

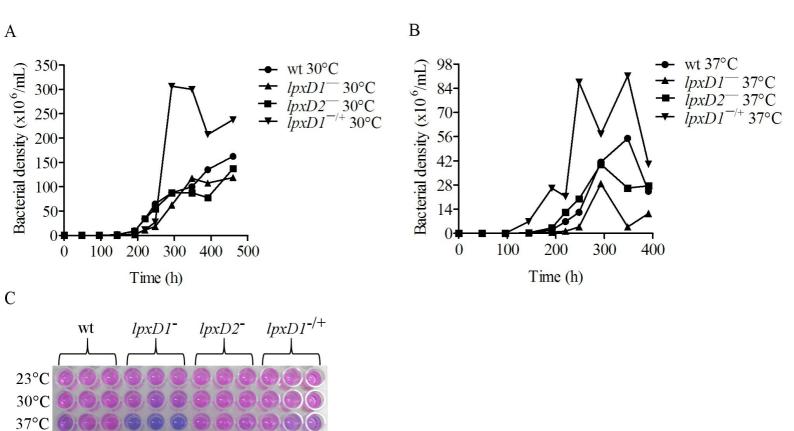

536 DEAE anion-exchange column. Mass spectra were obtained using the 60 mM ammonium acetate

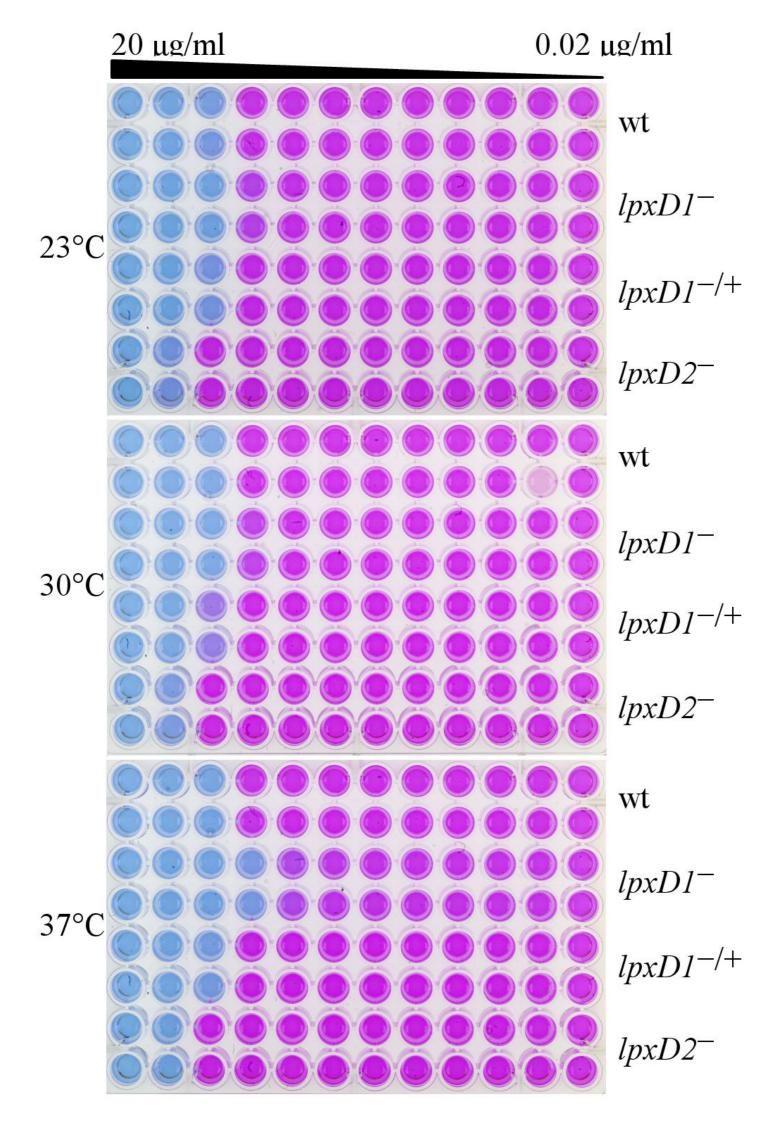

Manilae grown at 30°C. Lipid A isolated from each indicated strain was fractionated over a

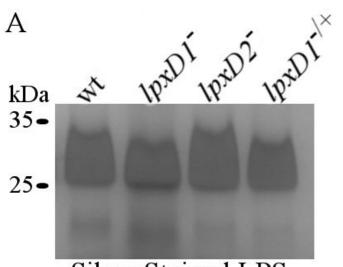

537 DEAE fraction for lipid A isolated from WT (A), $lpxDl^{-}$ (B), $lpxDl^{-/+}$ (C), and $lpxD2^{-}$ (D) L.

538 *interrogans* serovar Manilae. Each spectra is the average of >300 laser pulses. Based on relative

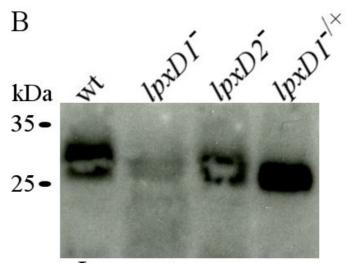

539 % signal intensity, the most abundant m/z peak for each isotopic cluster is labeled.
