- 17 Abstract
- 18
- 19 A group of six clinical isolates previously identified as Corynebacterium diphtheriae biovar Belfanti,
- 20 isolated from human cutaneous or peritoneum infections and from one dog, were characterized by
- 21 genomic sequencing, biochemical analysis and MALDI-TOF mass spectrometry. The six isolates were
- 22 negative for the diphtheria toxin gene. Phylogenetic analyses showed that the six isolates (including
- 23 FRC0190^T) are clearly demarcated from *C. diphtheriae*, *C. belfantii*, *C. ulcerans* and
- 24 *C. pseudotuberculosis.* The average nucleotide identity of FRC0190^T with *C. diphtheriae*
- 25 NCTC11397^T was 92.6%, and was 91.8% with *C. belfantii* FRC0043^T. *C. diphtheriae* subsp.
- 26 *lausannense* strain CHUV2995^T appeared to be a later heterotypic synonym of *C. belfantii* (ANI,
- 27 99.3%). Phenotyping data revealed an atypical negative or heterogeneous intermediate maltose
- 28 fermentation reaction for the six isolates. MALDI-TOF mass spectrometry differentiated the new
- 29 group from the other *Corynebacterium* taxa by the presence of specific spectral peaks. *rpoB* sequences
- 30 showed identity to atypical, maltose-negative C. diphtheriae biovar Belfanti isolates previously
- 31 described from two cats in the USA. We propose the name Corynebacterium rouxii sp. nov. for the
- 32 novel group, with FRC0190^T (= CIP 111752^{T} = DSM 110354^{T}) as type strain.

33 Introduction

34 The genus *Corynebacterium* currently includes approximately 111 species [1–3]. The most 35 important human pathogen of the genus is *Corynebacterium diphtheriae*, which causes diphtheria 36 [2,4]. C. diphtheriae is genetically heterogeneous [5–8] and four biovars were defined: Gravis, Mitis, 37 Belfanti and Intermedius [9–11], the latter being almost never reported in recent literature. In 2010, 38 maltose-non fermenting strains of C. diphtheriae biovar Belfanti were reported from two cats in the 39 USA, and were shown to have a divergent *rpoB* sequence [12]. In 2018, some biovar Belfanti isolates 40 were classified as a novel species, C. belfantii [3], with 94.85% average nucleotide identity (ANI) with 41 C. diphtheriae. Almost simultaneously, C. diphtheriae subsp. lausannense was also proposed for 42 strains of biovar Belfantii [13]. The tox gene, which codes for diphtheria toxin, is carried on a 43 corynephage that can lysogenize strains of C. diphtheriae. However, the tox gene was rarely reported 44 in isolates of biovar Belfanti [5,14,15] and no strain of C. belfantii or C. diphtheriae subsp. 45 lausannense was described as tox-positive [3][12]. The tox gene can also be harboured by strains of 46 C. ulcerans and C. pseudotuberculosis, two species that are phylogenetically close to C. diphtheriae 47 and C. belfantii [16]. Together, the above-mentioned species constitute a single phylogenetic clade nested within the Corynebacterium genus. We refer to this clade as the C. diphtheriae complex. 48 49 Here, we define the taxonomic status of six isolates initially identified as C. diphtheriae biovar 50 Belfanti, isolated from five human infections and one dog in France.

51 Material and Methods

We compared the six atypical clinical isolates, among which is strain FRC0190^T, with 13 *C. diphtheriae* strains of biovars Gravis or Mitis (including *C. diphtheriae* type strain NCTC 11397^T) and 8 strains previously [3] identified as *C. belfantii* (including the type strain FRC0043^T; **Table 1**; **Table S1**). Type strains of *C. ulcerans* (CIP 106504^T = NCTC 7910^T) and of *C. pseudotuberculosis* (CIP 102968^T = ATCC 19410^T) were also included for comparison.

57 Clinical samples or isolates were received at the French National Reference Centre for 58 Corynebacteria of the *diphtheriae* complex for isolation and/or characterization, respectively. Oxoid's 59 Tinsdale agar with supplement medium (Thermo Fisher Diagnostics, Dardilly, France) was used to isolate C. diphtheriae from clinical samples. Isolates were frozen in Brain-Heart-Infusion (BHI) 60 61 medium containing 30% of glycerol and stored at -80°C prior to this study. After thawing, isolates 62 were grown at 37°C on tryptose-casein soy agar plates during 24 hours. DNA was extracted from a 63 few colonies with the DNeasy Blood and Tissue kit (Qiagen, Hilden, Germany). The six isolates were 64 identified as C. diphtheriae by multiplex polymerase chain reaction (PCR) combining a dtxR gene fragment specific for C. diphtheriae [15] and a multiplex PCR [17,18] that targets a fragment of the 65 pld gene specific for C. pseudotuberculosis, the gene rpoB (amplified in all species of the 66 67 C. diphtheriae complex) and a fragment of 16S rRNA gene specific for C. pseudotuberculosis and C. ulcerans. The tox gene was also detected by PCR [19]. These PCR results were confirmed using a 68 69 more recent four-plex qPCR [20].

70 For biochemical identification, standard methods were used [21][14,22]. More specifically, 71 strains were characterized for pyrazinamidase, urease, nitrate reductase and for utilization of maltose 72 and trehalose using API Coryne strips (BioMérieux, Marcy l'Etoile, France) and the Rosco 73 Diagnostica reagents (Eurobio, Les Ulis, France) following provider's recommendations. The Hiss 74 serum water test was used for glycogen fermentation. Briefly, this test was performed as follows. 75 Solution A was obtained by dissolving 500 mg of bacteriological peptone (Oxoid, Hampshire, UK; ref. 76 LP0037) in 100 mL of distilled water, adding 100 mg of Na2HPO4 (Sigma-Aldrich, Saint-Louis, 77 Missouri, USA; ref: S7907), and homogenizing and heating the mixture until boiling. After cooling to 78 room temperature, 18 ml of sterile horse serum were added and mixed. In parallel, solution B was 79 prepared by adding 430 mg of acid fuchsin (Sigma-Aldrich, Saint-Louis, Missouri, USA, ref: F8129) 80 into 86 mL of distilled water, after which 14 mL of 30% NaOH (ThermoFisher Scientific, Waltham, 81 Massachusetts; ref. S/4950/PB15) were added. Solution B was stored up to 15 days in the dark. To 82 prepare the complete Hiss serum water sugar medium, 780 μ L of solution B were added to the total 83 volume of solution A. The pH was adjusted to 7.7 using HCl 5N (Sigma-Aldrich, Saint-Louis,

84 Missouri, USA; ref. H1758). 100 mg of glycogen (Acros Organics, Geel, Belgium, ref: 422950050) 85 were then added. The solution was mixed and distributed in 3.5 mL aliquots in 5 mL glass tubes, and 86 sterilized at 108°C during 30 minutes. This medium was conserved up to 6 months at $5^{\circ}C + 3^{\circ}C$. To 87 perform the glycogen test, a loopful (10 µL) of a bacterial culture from Columbia blood agar or 88 Tryptose-Casein-Soy agar was introduced into a tube containing 3.5 mL of sterile Hiss serum water 89 sugar medium. Results were read manually after homogenization of the suspension and incubation at 90 $37^{\circ}C + 2^{\circ}C$ during 24 h. Strains NCTC 12077 and NCTC 764 were used as positive and negative 91 controls, respectively (expected results: dark pink and light pink, respectively).

92 The biovar of isolates was determined based on the combination of nitrate reductase (positive 93 in Mitis and Gravis, negative in Belfanti) and glycogen fermentation (positive in Gravis only).

94 Antimicrobial susceptibility was characterized by the disk diffusion method using impregnated 95 paper disks (Bio-Rad, Marnes-la-Coquette, France) and minimum inhibitory concentrations were 96 determined using ETEST strips (BioMérieux, Marcy l'Etoile, France). The sensitivity was interpreted 97 using CA-SFM/EUCAST V.1.0 (Jan 2019) criteria for Corynebacterium (https://www.sfm-98 microbiologie.org/wp-content/uploads/2019/02/CASFM2019 V1.0.pdf). Susceptibility was tested for 99 the following antimicrobial agents: fosfomycin, vancomycin, kanamycin, gentamycin, penicillin G, 100 oxacillin, amoxicillin, imipenem, cefotaxime, clindamycin, azithromycin, spiramycin, clarithromycin, 101 erythromycin, clindamycin, ciprofloxacin, trimethoprim-sulfamethoxazole, trimethoprim, sulfonamide,

102 pristinamycin, rifampicin and tetracycline.

103 MALDI-TOF mass spectrometry was used for identification confirmation. For this purpose, an 104 overnight culture on Trypto-Casein-Soy Agar (TSA) (37°C) was used to prepare the samples 105 accordingly to the ethanol/formic acid extraction procedure proposed by in the manufacturer

106 recommendations (Bruker Daltonics, Bremen, Germany). The cell extracts were then spotted onto an 107 MBT Biotarget 96 target plate, air dried and overlaid with 1 μ L of a saturated α -cyano-4-

108 hydroxycinnamic acid (HCCA). 24 mass spectra per strain were acquired on a Microflex LT mass

109 spectrometer (Bruker Daltonics, Bremen, Germany). Re-analysis of the spectra was performed for the

110 purpose of this work. Spectra were first preprocessed by applying smoothing and baseline subtraction

111 with FlexAnalysis software using default parameters, exported as text files from the Brucker system

112 and then imported and analyzed in a dedicated BioNumerics v7.6.3 (Applied-Maths, Belgium)

113 database following the protocol described by Rodrigues et al. [23]. To allocate proteins to the specific

114 peaks detected, we extracted all the molecular weights from the genomes of the type strains

(NTCT11397^T, FRC0043^T and FRC0190^T) using a Biopython script 115

- 116 (https://biopython.org/DIST/docs/api/Bio.SeqUtils-module.html) and performed sequence alignments
- 117 with ClustalW for the candidate proteins.
- 118 Genomic sequencing was performed from Nextera XT libraries using a NextSeq-500
- 119 instrument (Illumina, San Diego, USA) with a 2 x 150 nt paired-end protocol. Contig sequences were
- 120 assembled using SPAdes v3.12.0 [24] (Table S1). JSpeciesWS [25] was used to calculate the BLAST-
- 121 based average nucleotide identity (ANIb). BLASTN was used to extract 16S rRNA and rpoB
- sequences from genome assemblies and to determine the presence or absence of the *narIJHGK* nitrate
- reduction gene cluster using as query the cluster of strain NCTC 13129 (RefSeq accession number:
- 124 DIP_RS13820 to DIP_RS13845) [26]. *rpoB* and 16S rRNA gene sequences of atypical *C. belfantii*
- strains from cats [12] were included for comparison. For genome-based phylogenetic analysis, the
- 126 pairwise *p*-distance (*i.e.*, proportion of aligned nucleotide differences) between each pair of genomes
- 127 was estimated based on Mash [27] using a multiple hit correction [28] with JolyTree
- 128 (<u>https://gitlab.pasteur.fr/GIPhy/JolyTree</u>). For 16S rRNA and rpoB gene sequences, sequences were
- aligned with MAFFT v7.407 [29] and the resulting alignment was used for phylogenetic tree inference
- 130 with IQ-TREE v1.6.7.2 [30] using the GTR+I+G4 model. Branch support was obtained after 1000
- 131 bootstrap replicates.

132 **Results and discussion**

Six isolates were isolated from five cutaneous lesions and one ascitic fluid sample (Table 1).
Strikingly, human cutaneous lesions were all ulcerations due to underlying chronic arteritis. Ascitic
fluid was sampled on a patient with a suspicion of spontaneous peritonitis. The dog was investigated in
the context of purulent orbital cellulitis.

137 The six isolates were tox negative (Table S1); more specifically, they were negative for 138 amplification of the expected 910-bp PCR product encompassing fragments A and B of the toxin gene 139 [19] and also negative for the amplification of a 117-bp region of diphtheria toxin fragment A [31] by 140 multiplex qPCR [20]. We also confirmed by BLASTN that the tox gene sequence (query: tox gene 141 sequence from strain NCTC 13129, RefSeq accession number: DIP RS12515) was absent from the 142 genomic assemblies. After species identification by multiplex PCR, the isolates were positive for dtxR 143 and rpoB and negative for C. ulcerans/C. pseudotuberculosis 16S rDNA and pld, leading to initial 144 identification as C. diphtheriae. Concordant with this identification, the six isolates were 145 pyrazinamidase, urease and trehalose negative. Upon biotyping, the isolates were nitrate and glycogen 146 negative, a pattern that corresponds to biovar Belfanti. Consistently, the *narKGHIJ* nitrate reduction 147 gene cluster was not detected from the genomic assemblies of these isolates and those of C. belfantii 148 (Table S2). The phenotypic aspect of colonies on Tinsdale or blood agar medium was undistinctive 149 from C. diphtheriae Mitis and Gravis and C. belfantii. However, we noted that similar to the Gravis 150 isolates, the colonies of the six atypical isolates looked dry and were friable on TCS medium. 151 Distinctively, the maltose test was negative for the six isolates using API Coryne (**Table S1**). The 152 same test was atypical using the Rosco Diagnostic method: results showed heterogeneous coloration 153 that was neither as yellow as the typically positive strains, nor as purple as the negative strains (Figure 154 S3). This atypical maltose result was not observed using API Coryne strips, with which the maltose 155 test was clearly negative for the six isolates. We noted that the four genes of the maltose utilization 156 pathway [32] are present and undisrupted in the six isolates, as in other members of the C. diphtheriae 157 complex. Further work is required to elucidate the mechanisms of maltose utilization and its 158 regulation, and why the two tests give different results.

Regarding their antimicrobial susceptibility (**Table S3**), the six isolates were resistant to fosfomycin, as is typical of *Corynebacteria* [33], and were susceptible to all other tested antimicrobial agents with the following exceptions: FRC0284 and FRC0527 were resistant to penicillin (minimum inhibitory concentration: 0.19 mg/L), and FRC0412 was resistant to penicillin and cefotaxime (0.19 mg/L and 1.0 mg/L, respectively). 164 Genomic sequencing results showed that the six isolates had a genome size of 2.4 Mb on 165 average (Table S1), similar to C. diphtheriae biovars Mitis and Gravis isolates (average size: 2.45 166 Mb), but smaller than C. belfantii (average size: 2.7 Mb). A genome sequence-based phylogenetic tree 167 (Figure 1) revealed three main clades. The first one contained all C. diphtheriae Mitis and Gravis 168 isolates, whereas the second comprised all C. belfantii isolates, and the third comprised the six 169 maltose-atypical isolates. The mean ANIb value of atypical isolates was 92.4% with the C. diphtheriae 170 clade and was 91.4% with C. belfantii (Table 2). These data indicate that the six isolates forming the 171 atypical clade correspond to a distinct genomic cluster, separated by a level of nucleotide divergence 172 that is well above the currently accepted genomic species threshold of ~94-96% [34,35]. The atypical 173 clade was genetically homogeneous, with ANIb values among the six isolates ranging from 99.21% to 174 99.94% (Table 2). Phylogenetic analysis of *rpoB* and 16S rRNA coding sequences was consistent with 175 the distinction of the atypical isolates from C. diphtheriae and C. belfantii (Figures S1 and S2). 176 However, the 16S rRNA gene sequence alignment showed only 3 insertions and 4 nucleotide 177 substitutions shared among the six atypical isolates as compared to C. diphtheriae, resulting in low 178 resolution of phylogenetic relationships (Figure S1). We noted that *rpoB* and 16S rRNA sequences of 179 previously reported atypical biovar Belfanti isolates from cats in the USA [12] were indistinguishable 180 from those of the atypical isolates from France, suggesting that the cat isolates from the USA belong to 181 the same novel group. Supporting this observation, the USA cat isolates were also reported as maltose 182 negative [12].

183 Recently, it was proposed that the *C. diphtheriae* taxon should be subdivided into two 184 subspecies, *C. diphtheriae* subsp. *diphtheriae* and *C. diphtheriae* subsp. *lausannense* [13]. Here, we 185 observed that the ANI value between the type strains of *C. diphtheriae* subsp. *lausannense* and *C.* 186 *belfantii* was 99.3%. Besides, the former was positioned within the phylogenetic branch of *C. belfantii* 187 (**Figure 1, S1 and S2**), and the descriptions of both taxa are very similar [3,13]. Given that *C. belfantii* 188 was validly published in October 2018, a few months before the taxonomic proposal *C. diphtheriae* 189 subsp. *lausannense* was validated

190 (https://www.microbiologyresearch.org/content/journal/ijsem/10.1099/ijsem.0.003174; January 2019),

191 the latter subspecies appears to be a later heterotypic synonym of *C. belfantii*.

192 Based on the MALDI Biotyper Compass database version 4.1.90 (Bruker Daltonics, Bremen,

193 Germany), the six isolates were identified as C. diphtheriae. However, detailed analysis of their

194 spectra led to the identification of six pairs of biomarkers (12 peaks corresponding to the same

195 proteins, with either single and double-charged ion forms) corresponding to three different proteins

196 within the range 3255–9495 m/z, which were associated either with the group of six isolates or with C.

197 *diphtheriae* and *C. belfantii* (Figure S4, Table S4). We presumptively identified the specific

198 biomarkers as two ribosomal proteins, L30 and S20, and one putative stress response protein (CsbD).

199 Consistently, their amino-acid sequences differed between the C. rouxii on the one hand, and

200 *C. diphtheriae/C. belfantii* on the other hand (Figure S5). Based on the current dataset, the specificity

and sensitivity of peak distribution among the three species ranged between 95–100% and 76–100%,

respectively (**Table S4**). MALDI-TOF MS thus allows the discrimination between *C. rouxii* and *C.*

203 *diphtheriae/C. belfantii*. These results warrant future updates of reference MALDI-TOF databases to
 204 incorporate the novel taxon.

Based on the above results, the isolates of the novel clade represent a novel species, which we propose to name *Corynebacterium rouxii*.

Description of *Corynebacterium rouxii* sp. nov. (rou'.xi.i. N.L. gen. n. *rouxii*, of Roux, a French
 scientist and former director of Institut Pasteur who made critical contributions to diphtheria toxin
 discovery and antitoxin treatment).

210 C. rouxii conforms biochemically to the description of C. diphtheriae strains belonging to 211 biovar Belfanti [2,21], except that strains are negative for maltose fermentation (API Coryne), being 212 nearly negative or weakly positive with the Rosco Diagnostica maltose test. Key characteristics that 213 distinguish C. rouxii from other members of the C. diphtheriae complex are specific MALDI-TOF MS 214 biomarkers as described herein. The G+C content of C. rouxii genomes ranges from 53.2% to 53.3%, 215 with a value of 53.3% for the type strain. So far, strains were isolated from 5 humans and a dog in 216 France, as well as from two related cats in the USA. The type strain is $FRC0190^{T}$ (= CIP 111752^{T} = DSM 110354^{T}), isolated in 2013 from a foot 217

ulceration reported in Cahors, France. The genome accession number of strain FRC0190^T is
 ERS3795540.

- **Figure 1.** Phylogenetic relationships derived from the analysis of genomic sequences.
- 355 The phylogenetic tree and branch supports were inferred using JolyTree [28]
- 356 (https://gitlab.pasteur.fr/GIPhy/JolyTree). Strains *C. ulcerans* NCTC 7910^T and *C. pseudotuberculosis*
- 357 ATCC 19410^{T} were used as outgroup as they are the closest phylogenetic neighbors to *C. diphtheriae*,
- 358 *C. belfantii* and *C. rouxii*. Branch support is indicated using grey circles (see key; only values >50 are
- 359 shown). Each taxonomic type strain is shown in bold; note that *C. diphtheriae* subsp. *lausannense* type
- 360 strain falls within *C. belfantii*. The scale bar corresponds to an estimated evolutionary distance of 0.01.

361

362 **Figure S1.** Phylogenetic analysis of 16S rRNA gene sequences.

363 16S rRNA gene sequences of *C. rouxii* isolates have accession numbers MN535982 to MN535987

364 (Table S1). C. diphtheriae strains isolated from domestic cats in the USA [12] were added for

365 comparison (strain codes CD443-CD450; GenBank accession numbers: FJ409572 to FJ409575). Each

taxonomic type strain is shown in bold. The scale bar indicates the number of substitutions per site.

- 367 The sizes of grey circles correspond to bootstrap support of branches (-b 1000 option in IQ-TREE) as
- indicated by the key.
- 369
- 370 **Figure S2.** Phylogenetic analysis of *rpoB* coding sequences.

371 *rpoB* gene sequences of *C. rouxii* isolates have accession numbers MN542347 to MN542352 (Table

372 **S1**). *C. diphtheriae* strains isolated from domestic cats in the USA [12] were added for comparison

373 (strain codes CD443 and CD450; GenBank accession numbers: FJ415317 and FJ415318). Each

taxonomic type strain is shown in bold. The scale bar indicates the number of substitutions per site.

- The sizes of grey circles correspond to bootstrap support of branches (-b 1000 option in IQ-TREE) as
- indicated by the key.
- 377

378 **Figure S3.** Maltose fermentation results.

The maltose test was performed using the Rosco Diagnostica reagents. Tube 1: NCTC 10648, *C*.

380 *diphtheriae* biovar Gravis; Tubes 2 to 7: *C. rouxii* isolates FRC0071, FRC0297, FRC0284, FRC0527,

381 FRC0190, FRC0412; Tube 8: NCTC 10356, *C. belfantii*; Tube 9: NCTC 12077 (*C. ulcerans*, positive

382 control); Tube 10: NCTC 764 (*C. striatum*, negative control).

383

Figure S4. Peak positions (*m*/*z*) observed for strains of C. *diphtheriae*, C. *belfantii* and C. *rouxii*. Stars
denote those peaks that are useful for species identification, as detailed in the corresponding
supplementary Table.

387

Figure S5. Amino acid sequence alignments and the respective molecular weight of the proteins presumptively associated with specific MALDI-TOF MS peaks detected in *Corynebacterium*

390 *diphtheriae, C. belfantii* and *C. rouxii*

391
