48 **ABSTRACT**

49

50 Invasive listeriosis is a severe food-borne infection in humans with increasing incidence world-
51 wide. The disease is difficult to control from the public health perspective, but molecular
52 surveillance programs have been implemented by different countries for improving recognition
53 and management of listeriosis outbreaks. Routine whole genome sequencing (WGS), core
54 genome multi locus sequence typing (cgMLST) and single nucleotide polymorphism (SNP)
55 calling were used for subtyping of *L. monocytogenes* isolates from listeriosis cases and suspected
56 foods in Germany. This identified an unusually large cluster of *L. monocytogenes* isolates with
57 134 highly clonal, benzalkonium-resistant ST6 isolates collected in 2018-2019 and allocated to
58 112 notified listeriosis cases. Epidemiological investigations identified blood sausage as the
59 outbreak vehicle, which was contaminated with isolates highly related to the clinical isolates.
60 Withdrawal of the product from the market ended the outbreak. This cluster represents one of the
61 largest European outbreaks of invasive listeriosis in the last 25 years.

62 INTRODUCTION

63

64 Listeriosis is a severe, mainly foodborne human infection associated with high case fatalities and
65 hospitalization rates when compared to other bacterial gastrointestinal pathogens (1). The
66 causative agent, *Listeria monocytogenes*, occurs ubiquitously in the environment and
67 disseminates into the food production chain. Patients develop either self-limiting non-invasive
68 gastroenteritis (2, 3) or invasive listeriosis. Listeriosis affects mainly elderly,
69 immunocompromised patients and pregnant women, causing a severe invasive form of the
70 disease leading to sepsis, meningitis, and encephalitis or neonatal infections, and miscarriage (4).
71 Case fatality rates of invasive listeriosis are around 30% for neurolisteriosis and even higher in
72 septic patients (5). In Europe and North America, invasive listeriosis affects 0.3-0.6 patients per
73 100,000 inhabitants per year (6, 7).

74 *L. monocytogenes* forms hard-to-remove biofilms in food-processing plants, can acquire
75 tolerance to sanitizers and multiplies even at refrigeration temperatures (8). These properties
76 complicate efficient prevention of *L. monocytogenes* contaminations in different types of ready-
77 to-eat products: dairy, meat and fish as well as in fruits and vegetables, all of which have caused
78 listeriosis outbreaks in the past (9-12).

79 Outbreaks of listeriosis are difficult to control for several reasons: First, case numbers are low,
80 impairing the generation of valid hypotheses on possible food sources through patient interviews.
81 Second, incubation time can be lengthy (1-67 days) (13), and patients are often seriously ill,
82 further complicating patient interviews. Third, the large variety of possible food sources makes
83 pinpointing through patient interviews and the follow-up tracing of food difficult. Moreover,
84 listeriosis outbreaks can be geographically widespread due to long-distance food trade
85 connections, e-commerce, and traveling, thus hampering outbreak recognition by local authorities

86 (10, 14, 15). Finally, listeriosis outbreaks can be protracted and may last for several years (16),
87 making it difficult to identify affected patient groups correctly and to allocate the common source
88 of infection.

89 Nationwide systematic collection of *L. monocytogenes* isolates from human listeriosis cases and
90 their subtyping using high-resolution WGS-based typing techniques allows for rapid and reliable
91 detection of outbreak clusters (3, 17-22), some of which were not detectable in the past. At the
92 same time, systematic and on-demand typing of food-associated *L. monocytogenes* isolates assists
93 in detecting outbreak sources. In a recent French molecular surveillance study, one-third of all
94 isolates were grouped into WGS clusters and the majority of these clusters contained less than 5
95 isolates (20). Larger outbreaks of invasive listeriosis occur, although infrequently, and two of the
96 world's largest outbreaks in the recent past included 147 cases in a multi-state US outbreak
97 (2011) associated with cantaloupe melons (10) and 1,060 cases in a South African outbreak
98 (2017-2018) associated with French polony sausage (11). Since August 2019, Spain has been
99 experiencing another large listeriosis outbreak (23). However, the scientific evaluation of this
100 outbreak needs to be awaited.

101 Here we present an exceptionally large nation-wide outbreak with 134 laboratory-confirmed
102 isolates allocated to 112 patients with epidemiological investigations and complementary WGS-
103 based typing of food isolates identifying the outbreak vehicle. This outbreak represents one of the
104 largest outbreaks of invasive listeriosis in Europe documented in the scientific literature during
105 the last 25 years.

106 **METHODS AND MATERIALS**

107

108 **Bacterial strains and growth conditions.**

109 All 184 *L. monocytogenes* isolates are listed in Table S1. *L. monocytogenes* strains were routinely
110 cultured at 37°C in brain heart infusion (BHI) broth, on BHI or sheep blood agar plates.

111

112 **Isolation of food isolates**

113 Detection and enumeration of *L. monocytogenes* from food samples was performed according to
114 EN ISO 11290 parts 1 and 2. The species was confirmed according to ISO standard 11290-
115 1:2017 or MALDI-TOF-MS, and a previously described multiplex PCR (24).

116

117 **Determination of molecular serogroups**

118 The GenElute Bacterial Genomic DNA Kit (Sigma) or the QIAamp DNA Mini Kit (Qiagen) was
119 used to isolate chromosomal DNA. Molecular serogroups were determined by multiplex PCR
120 (25).

121

122 **Genome sequencing, multi locus sequence typing (MLST) and core genome MLST
123 (cgMLST)**

124 DNA was quantified using the Qubit dsDNA BR (or HS) Assay kit and Qubit fluorometers
125 (Invitrogen). Libraries were prepared using the Nextera XT DNA Library Prep Kit (Illumina).
126 Isolates were sequenced on MiSeq, HiSeq, or NextSeq sequencers. Raw reads were trimmed and
127 assembled in SeqSphere using the Velvet assembler. *In silico* serogroups, MLST sequence types
128 (STs) and 1,701 locus cgMLST complex types (CTs) were extracted using the Ridom SeqSphere
129 Software through automated allele submission to the *L. monocytogenes* cgMLST server

130 (<http://www.cgmlst.org/ncs/schema/690488/>) (26). Coverage ranged between 22- and 116-fold
131 (median 54-fold). cgMLST clusters were defined as groups of isolates with ≤ 10 different alleles
132 between neighboring isolates. UGPMA trees were calculated in SeqSphere in the “pairwise
133 ignore missing values” mode.

134

135 **SNP-based alignments**

136 Mapping of sequencing reads, generation of consensus sequences, alignment calculation, and
137 SNP filtering (exclusion distance = 300) were performed using in-house pipelines (17). The 10-
138 092876-0769 LM12 genome (NZ_CP019625, serogroup IVb, ST6, CT6304) was used as
139 reference. Generation of maximum likelihood trees was performed using the Geneious 9.1.3 Tree
140 builder (Biomatters Ltd.) and the RAxML plugin.

141

142 **Virulome and resistome analysis**

143 Virulence and resistance genes of *L. monocytogenes* were included as target loci in SeqSphere
144 task templates as previously described (17, 27). Targets were extracted from assembled contigs
145 using SeqSphere, and alleles were considered to be present when identity was $>90\%$ and at least
146 99% of the reference sequence aligned with the query sequence.

147

148 **Antibiotic susceptibility testing**

149 Antibiotic susceptibility testing was performed by a microdilution assay in a 96 well plate format
150 in accordance with EUCAST guidelines in Mueller Hinton Fastidious (MH-F) broth (28). The
151 overall plate design was adopted from a study by Noll et al. (29).

152

153 **Determination of tolerance to disinfectants**

154 *L. monocytogenes* isolates were spread on BHI agar plates. Cellulose discs (6 mm in diameter)
155 were loaded with 10 µl of a 10 mg/ml aqueous benzalkonium chloride solution and placed on top
156 of the agar plate. Plates were incubated overnight at 37°C and growth inhibition zone diameters
157 were determined. Statistical significance was tested by Student's *t*-test.

158

159 **Case-control study**

160 Outbreak cases were defined as patients reported to public health authorities and transmitted to
161 the Robert Koch Institute with disease onset between August 2018 and June 2019, with isolation
162 of *L. monocytogenes* from normally sterile body fluids or in birth settings and confirmation by
163 cgMLST and SNP-analysis. *L. monocytogenes* isolates were sent to the Robert Koch Institute and
164 notification and typing data were merged for investigation. After identification of the outbreak,
165 patients were interviewed using a standardized questionnaire on food consumption during the two
166 weeks before the onset of illness, general eating habits, and food purchasing behaviors. Based on
167 these data, 40 food items were included in the case-control study. Controls were contacted and
168 interviewed by a survey institute. The controls were frequency matched to the case patients for
169 age, gender and place of residence (federal state). Food items with p-value ≤ 0.05 that were
170 consumed by more than 50% of the subjects were considered for multivariable analysis. The
171 stepwise-backward approach for model formation was that food items, which were no longer
172 significantly associated, were consecutively excluded from the multivariable model until only
173 significantly associated foods and their confounders remained. Risk measures (odds ratios,
174 univariable and multivariable) were determined in the statistical analysis.

175

176 **Data availability**

177 Genome sequences are available at the European nucleotide archive (<https://www.ebi.ac.uk/ena>).

178 Accession numbers are listed in Table S1.

179

180 **RESULTS**

181

182 **Detection of a large human listeriosis cluster by molecular surveillance**

183 The binational German-Austrian Consultant Laboratory for *L. monocytogenes* collects isolates
184 from approximately two-thirds of all mandatorily-notified German listeriosis cases (701 cases in
185 2018), and sequences their genomes. cgMLST identified a phylogenetically diverse cluster
186 (designated “Epsilon1”) with 46 PCR serogroup IVb isolates belonging to MLST ST6 and
187 cgMLST complex types (CT) 90, 2981, 3803, 3805, 3806, 3921, 4083, 4465, 6236, 6331, 7353,
188 and 7451, all defining specific allelic profiles within a CT threshold of ≤ 10 different alleles (17,
189 26). This cluster included isolates from 2011-2019 collected from all over Germany without any
190 apparent geographical concentration. Allelic distances between these isolates varied from 0-25
191 (median: 11). In autumn 2018, a sudden increase of CT4465 and CT7353 isolates belonging to
192 the Epsilon1 cluster was detected. Furthermore, the numbers of listeriosis cases reported in
193 calendar weeks 34-43, 46, 48, and 50 exceeded the median of the five previous years (Fig. S1).
194 To identify the outbreak clone among all incoming PCR serogroup IVb isolates, a clone-specific
195 PCR was developed (supplementary information). Altogether, 134 clinical CT4465 and CT7353
196 isolates were collected between August 2018 and April 2019. These isolates formed a remarkably
197 homogenous cluster with only 0-5 (median: 0) different cgMLST alleles (Fig. 1). In contrast, two
198 earlier CT4465 isolates collected in June 2018 and July 2017 differed in 9-15 alleles (Fig. 1).
199 Raw sequencing reads of all Epsilon1 strains were mapped against the 10-092876-0769 LM12
200 genome as the most closely related, completed genome available. SNP calling separated the
201 Epsilon1 cluster into several sub-clusters, but all CT4465 and CT7353 isolates collected from
202 August 2018 onwards formed a single cluster (Fig. S2). This sub-cluster was named Epsilon1a,
203 and SNP distances within this cluster ranged between 0-3 SNPs (median: 0). The two earlier

204 CT4465 isolates were separated from the Epsilon1a cluster with 6-10 SNPs difference (median:
205 8). Thus, SNP calling supports the detection of a cluster of closely related CT4465 and CT7353
206 strains. Interestingly, only 21-29 cgMLST alleles (median 26) and 8-12 SNPs (median 8) differed
207 between the Epsilon1a clone and the South African outbreak strain (CT5886, Fig. 1, Fig. S2).

208

209 **Description of the patient collective**

210 The 134 isolates could be allocated to 112 patients according to the case definition. Initial cases
211 were reported in August 2018, with the outbreak peaking in September 2018 (Fig. 2A). The last
212 case was notified in April 2019 (as of 25th March 2020). Cases occurred in 11 of 16 federal states
213 in Germany with the majority of the cases occurring in Western and Southern Germany (Fig. 2B).
214 This outbreak and the assembled genome of one representative isolate (isolate ID: 18-04540)
215 were communicated via the European Epidemic Intelligence Information System (EPIS) platform
216 on 23rd October 2018 (UI-516). France, as the only other country involved, reported an
217 Epsilon1a listeriosis patient who had travelled to Germany and purchased food there. Sequence
218 data of isolate 18-04540 was submitted to ENA (SAMEA5041142). The closest related isolate
219 available at the National Center for Biotechnology Information (NCBI) pathogen detection
220 pipeline was a Dutch clinical isolate from 2016 with a SNP distance of 12, which was clearly
221 above the SNP distances observed within the Epsilon1a cluster.

222 There were 66 men (59%) among 111 non-pregnancy-associated outbreak patients. Seven
223 patients died (6.3%), two of them with listeriosis as the primary cause. One Epsilon1a isolate
224 originated from a pregnant woman (0.9%). Gestational age and health outcome of the newborn
225 were not reported. The remaining isolates came from adult patients aged 53-98 years (median 79
226 years). The age distribution was not noticeably different from other notified listeriosis cases. Of
227 the 134 Epsilon1a isolates, 99 were isolated from blood samples, 13 from cerebrospinal fluid, one

228 each from lymph nodes, ascites, sputum, pleura, joints, abscesses, or a superficial wound (Table
229 S1). The type of isolation source for the remaining 15 isolates is not known.

230

231 **Properties of the outbreak clone**

232 Virulome analysis revealed the presence of *Listeria* pathogenicity island 1 (LIPI-1) in all
233 Epsilon1a outbreak isolates and detected the complete listeriolysin S-encoding pathogenicity
234 island LIPI-3 in 64% of them. In contrast, LIPI-4, encoding a putative phosphotransferase system
235 associated with neurolisteriosis (30), was not present (Fig. S3). The Epsilon1a clones carried the
236 same complement of internalin genes as other PCR serogroup IVb strains (Fig. S3). Susceptibility
237 testing revealed sensitivity towards most clinically relevant antibiotics, however all tested isolates
238 were fully resistant to ceftriaxone and daptomycin (Tab. S2). This is consistent with the intrinsic
239 resistance of *L. monocytogenes* and the absence of additional resistance determinants, as
240 suggested by the resistome approach (Fig. 3A). Further resistome analysis demonstrated the
241 prevalence of the *emrC* gene associated with benzalkonium chloride tolerance (Fig. 3A). In full
242 agreement with this observation, increased tolerance of the Epsilon1a and Epsilon1 isolates to
243 benzalkonium chloride was shown when compared to other ST6 or PCR serogroup IVb isolates
244 not belonging to the Epsilon1/1a clusters (Fig. 3B).

245

246 **Investigations for identifying the outbreak vehicle**

247 In our case-control study, 41 cases and 155 controls were included. A total of 40 out of 41 (98%)
248 cases reported that they had purchased food in stores of one specific supermarket chain, in
249 contrast to 99 out of 154 controls (odds ratio 22.5; p-value = 0.003, 95% CI: 2.9-174.9). Other
250 supermarket chains were not associated with these cases. Thus, only cases and controls that had
251 purchased food from this specific supermarket were included in further analyses. In the fourth

252 calendar week of 2019, a strong association of cases with the consumption of minced meat (odds
253 ratio of 42.4; p-value = 0.001, 95% CI: 4.3-415.4) and blood sausage (odds ratio of 23.1; p-value
254 = <0.001, 95% CI: 4.3-123.5; Table 1) was detected. A total of 90% of the cases reported having
255 consumed minced meat (45% of controls) and 80% of the cases blood sausage (23% of controls).
256 There were no vegetarians among the cases.

257 In order to perform risk-oriented screening, food samples were collected in supermarkets and the
258 households of some patients, according to the results of the epidemiological investigations. In one
259 case, *L. monocytogenes* could be detected in three open samples from a patient's refrigerator.
260 Among these, sliced blood sausage purchased at the incriminated supermarket chain showed the
261 highest contamination ($>3 \times 10^6$ CFU/g). This led to another round of intensified screening of
262 prepacked blood sausage. In calendar week 7 (2019), *L. monocytogenes* was found in an original
263 sealed package of sliced blood sausage (<10 CFU/g) and in a second blood sausage sample of the
264 same manufacturer. In total, five isolates from patients' households food items and from blood
265 sausage samples grouped with clinical Epsilon1a isolates after cgMLST (0-3 different alleles,
266 median=0) and SNP calling (0-2 SNPs, median=0) (Fig. 1, Fig. S2). The blood sausage was
267 produced by a big German meat and sausage manufacturer and sold in large parts of the country.
268 The product was withdrawn from the market on 12th February 2019, and the last clinical
269 Epsilon1a isolate was collected on 18th April 2019. In contrast, Epsilon1 isolates not belonging to
270 the Epsilon1a cluster caused disease even after the end of the Epsilon1a outbreak. The plant was
271 cleaned and disinfected. Thereafter, *L. monocytogenes* was not detected in several hundred
272 official and ~2.500 own control samples taken from products or the production site.

273 **DISCUSSION**

274

275 The Epsilon1a outbreak is the largest outbreak of listeriosis ever identified in Germany and
276 represents one of the largest outbreaks of invasive listeriosis in Europe documented in more than
277 25 years. The last reported European outbreak of invasive listeriosis of the same order of
278 magnitude dates back to 1992-1993 when 247 patients were infected in France with a serotype 4b
279 clone that contaminated pork tongue in aspic (31). Cantaloupe melons were the vehicle in the
280 large US outbreak in 2011, which was caused by five different clones (10). In contrast, the single
281 clone causing the world's largest outbreak in South Africa showed strong clonality. The genomes
282 of 326 isolates from this outbreak only differed in ≤ 4 cgMLST alleles (11). Likewise, only a
283 single clone was associated with the Epsilon1a outbreak, and high clonality was observed among
284 its isolates. The mutation rate in the natural *L. monocytogenes* population is 2.6×10^{-7}
285 substitutions/site/year (27) so that one SNP can be expected per year on average and genome for
286 *L. monocytogenes* strains under natural conditions. The high clonality could imply that the
287 outbreak clone may only have persisted in the production facility without rapid multiplication.
288 Purchases in a particular supermarket chain and consumption of blood sausage were strongly
289 associated with listeriosis in the case-control study and the outbreak clone was identified in blood
290 sausage samples from a patient's household and from the incriminated supermarket chain. Blood
291 sausage is heat-treated during production, so contamination likely occurred post-production,
292 possibly during slicing or packaging. The shelf-life of sliced blood sausage is short (several days
293 to few weeks) (32), and the amount of *L. monocytogenes* found in unopened blood sausage
294 samples was below the limit of 100 CFU/g. Storage beyond the anticipated shelf-life or
295 insufficient refrigeration might have allowed *L. monocytogenes* multiplication inside the vehicle;
296 this only could have been prevented by a zero tolerance policy. The type of the vehicle could also

297 explain the low number of pregnant women (1 out of 112) since typically pregnancy-related
298 listeriosis accounts for ~7% among all listeriosis cases (33): Pregnant women should be cautious
299 with sliced sausage according to official recommendations (34).

300 Analysis of the Epsilon1a genome has yielded some insights into the infectivity of this clone, as it
301 belongs to sequence type ST6. *L. monocytogenes* ST6 clones were first isolated in 1990 (35),
302 caused various outbreaks in the past, including the large South African outbreak, and are
303 associated with an unfavorable outcome of meningitis (36). The Epsilon1a clone and the South-
304 African outbreak strain are closely related. Thus, two descendants of the same historic *L.*
305 *monocytogenes* ancestor have spread globally and contaminated food production facilities on two
306 different continents. The Epsilon1a clone carried the *emrC* gene, which is the presumable cause
307 of its increased benzalkonium chloride tolerance (37). Benzalkonium chloride was banned in the
308 EU as a disinfectant in 2016 (38), but its use in the past might have selected tolerant strains.

309 The identification of this outbreak and its vehicle resulted from an efficient collaboration between
310 public health and food safety authorities in Germany. Several requirements had to be met first for
311 successful outbreak clarification: (i) developing a mandatory notification system to facilitate
312 systematic patient interviews with an efficient questionnaire to generate hypotheses on possible
313 food sources, (ii) implementing a WGS-based molecular surveillance program for reliable
314 identification of outbreak clusters by public health authorities, (iii) systematically collecting of
315 food isolates from internal controls and on-demand investigations and their subtyping using
316 harmonized WGS-based methodology by food safety authorities, and (iv) continuously
317 exchanging information on outbreak clusters between the institutions involved. With these
318 prerequisites at hand, the causative food vehicles for five out of the six biggest listeriosis clusters
319 that occurred in 2014-2019 in Germany have been identified, and it is questionable whether this
320 would have been possible in pre-WGS times. Nevertheless, routinely conducted interviews of

321 listeriosis cases regardless of outbreaks would probably have enabled a faster identification of the
322 outbreak vehicle. In our opinion the course of the Epsilon1a outbreak is a good example to
323 demonstrate how WGS-based pathogen surveillance combined with efficient interventions of the
324 involved stakeholders can improve management and prevention of foodborne infectious diseases
325 in general.

326

327 **FUNDING**

328

329 This project was supported by the intensified molecular surveillance initiative of the Robert Koch
330 Institute (2016-2018, to AF and KS, grant number: 832133) and grants of the German Ministry of
331 Health (to SH, grant number: ZMVII-2518NIK703, and to AF and SK, grant number:
332 MolTypList). The funders had no role in study design, data collection and analysis, decision to
333 publish, or preparation of the manuscript.

335 **ACKNOWLEDGEMENTS**

336

337 We are grateful to Andrea Thürmer for sequencing support and would like to thank Birgitt Hahn
338 and Simone Dumschat for excellent technical assistance, and Yvonne Pfeiffer for help with some
339 experiments. We thank Karan Gautam Kaval for the critical reading of the manuscript.

340

341 **BIOGRAPHICAL SKETCH**

342

343 PD Dr. Sven Halbedel is a molecular microbiologist in the Division of Enteropathogenic bacteria
344 and *Legionella* at the Robert Koch Institute in Wernigerode and is the deputy head of the German

345 consultant laboratory for *Listeria*. His research focuses on physiology, virulence and
346 epidemiology of *L. monocytogenes*.

461

462 **FIGURE LEGENDS**

463

464 **Figure 1: Identification of the Epsilon1a outbreak cluster by cgMLST.**

465 UPGMA tree calculated using cgMLST data of Epsilon1 isolates (red) and the Epsilon1a sub-
466 cluster (green - clinical isolates, blue - food isolates). Two earlier CT4465 isolates (July 2017 and
467 June 2018) not belonging to Epsilon1a are shown in pink. Strain 10-092876-0769 LM12 (used as
468 reference genome for SNP calling) shown in Fig. S2 is included for comparison (black). South
469 African outbreak isolates (11) are shown in orange.

470

471 **Figure 2: Spatial and temporal distribution of outbreak cases.**

472 (A) Diagram showing the number of Epsilon1a isolates received by the consultant laboratory per
473 week. CW - calendar week. (B) Geographical distribution of laboratory-confirmed Epsilon1a
474 cases within Germany.

475

476 **Figure 3: Tolerance of Epsilon1a isolates to benzalkonium chloride.**

477 (A) Resistome analysis of clinical *L. monocytogenes* Epsilon1 and Epsilon1a isolates. Assembled
478 genome sequences were searched for genes known to confer resistance to sanitizers, heavy
479 metals, and antibiotics using a SeqSphere task template. Genomes of strains EGD-e
480 (NC_003210.1), L2624 (NZ_CP007686) FORC_049 (NZ_CP016629), 6179 (NZ_HG813249),
481 LM201 (AYPT000000000), 2012-0070 (MNCF000000000), NCTC 10887 (MWLR000000000), 10-
482 092876-0731 LM5 (NZ_CP019618), and 12754_4#74 (ERR564017) + pLMST6
483 (Hx2000053471) were included for comparison. Abbreviations: QACs - quaternary ammonium
484 compounds, sm – streptomycin, cap – chloramphenicol, erm – erythromycin, fos – fosfomycin,
485 lin – lincomycin, flu – fluoroquinolones, tet – tetracycline, cfx – ceftriaxone. Please note that the

486 *emrC* gene is located on plasmid pLMST6, which is present in certain ST6 strains (39). Its
487 location on a plasmid may explain why it was not detected throughout the entire Epsilon1a
488 population due to plasmid loss. (B) Increased resistance of Epsilon1a and Epsilon1 isolates to
489 benzalkonium chloride. Three representative isolates belonging to human listeriosis clusters
490 Epsilon1a, Epsilon1, and distinct listeriosis clusters Lambda2 (ST2, CT2402), Pi3 (ST217,
491 CT5744) or Theta3 (ST249, CT4449) were tested for resistance to benzalkonium chloride by disc
492 diffusion. Three representative ST6 isolates, not belonging to Epsilon1, were also included.
493 Results of three independent replicates for all three isolates per group are shown. The asterisk
494 indicates statistically significant differences to Epsilon1a ($P \leq 0.01$, *t*-test).
495

496 **Table 1:** Results of multivariable analysis of food consumption from a case-control study during
 497 the Epsilon1a listeriosis outbreak, Germany 2018-2019. Only 40/41 cases and 99/155 controls
 498 that confirmed shopping at the incriminated supermarket chain were included.

Food item	Odds Ratios (multivariable*)	95% Confidence intervall	p-value
Minced meat	42.4	4.3-415.1	0.001
Blood sausage	23.1	4.3-123.5	<0.001
Cold cuts (roast pork / Kassler)	15.4	2.9-82.1	0.001
Edamer cheese	7.3	1.6-32.8	0.009
smoked ham #	0.06	0.0-0.4	0.003
hard cheese #	0.2	0.0-0.9	0.038

499 * adjusted for age, gender, geography (north/south).

500 # smoked ham and hard cheese are confounders for cold cuts and Edamer cheese.

15

16 **A diagnostic PCR for identification of the outbreak clone**

17 The median turn-around time (time from arrival of a sample in the consultant laboratory until
18 genome sequencing results) was 34.5 days in the course of this investigation. Therefore, we
19 searched for DNA regions specific for Epsilon1a isolates in order to identify Epsilon1a clones by
20 PCR and to prioritize samples for genome sequencing and to initiate patient interviews without
21 delay. For this purpose, the contigs of three Epsilon1a isolates (target) and of 50 non-Epsilon1a
22 isolates of PCR serogroup IVb (non-target) were analyzed by the RUCS 1.0 algorithm, designed
23 to identify primer pairs for unique core sequences present in a target genome dataset and absent
24 in a set of non-target genomes. (1) This approach identified a 262 bp fragment specific for the
25 chosen target genomes that could be amplified using the primers Eps-1-fw
26 (AGTCGTCTTTAGTGCGCTGAA) and Eps-1-rev (TAGGTCTGTTGATGGCACCAC). The
27 applicability of this primer set was tested using 16 genome sequences of Epsilon1a and 12 of
28 non-Epsilon1a PCR serogroup IVb clones. Experimentally determined sensitivity of the PCR
29 system was 94%, while its specificity was 75%. The 262 bp fragment is part of an open reading
30 frame encoding a phage tail length tape measure protein, which was detected in 119 out of 134
31 Epsilon1a strains (89%) according to genomic data. In contrast, among 662 analyzed PCR
32 serogroup IVb genomes, this phage tail open reading frame was only found in 20 ST6 genomes
33 that did not belong to the Epsilon1a group (3%). Thus, the Eps1a PCR was used to identify
34 possible Epsilon1a isolates among the incoming PCR serogroup IVb isolates to prioritize them
35 for WGS. Out of the 67 PCR serogroup IVb isolates that had been tested by the Eps1a PCR
36 during the outbreak, only 11 turned out to be false-positive (16%).

42 Abbreviations: CSF - cerebrospinal fluid, GS - gynaecological swab, PF - pleural fluid, BA -
43 brain abscess. Please not that isolates from non-sterile materials were not included in the outbreak
44 description.

45 **Table S2:** Antimicrobial susceptibility in the Epsilon1a outbreak cluster (n= 79).

RAM ¹		79												
TET ¹						4	75							
TGC ²		1	77	1										
CTX	79													
VAN ¹						74	5							

46 All 79 strains were tested against 14 antibiotics. Underlined values indicate no observable growth
 47 at the lowest tested concentration. Concentrations in grey areas were not tested. Vertical lines
 48 indicate resistance breakpoints as defined by EUCAST for *Listeria monocytogenes*,
 49 *Streptococcus pneumoniae* (1) or *Staphylococcus aureus* (2). Intermediate concentration values
 50 between resistant and susceptible organisms are hatched.

51 Abbreviations: AMP - ampicillin, PEN - benzylpenicillin, CRO - ceftriaxone, CIP -
 52 ciprofloxacin, DAP - daptomycin, ERY - erythromycin, GEN - gentamicin, LIN - linezolid, MER
 53 - meropenem, RAM - rifampicin, TET - tetracycline, TGC - tigecycline, CTX - cotrimoxazole
 54 (trimethoprim/ sulfamethoxazole), VAN - vancomycin.
